NATURE

A WEEKLY

ILLUSTRATED JOURNAL OF SCIENCE

VOLUME XXIV.

MAY 1881 to OCTOBER 1881

"*To the solid ground*
Of Nature trusts the mind which builds for aye."—WORDSWORTH

London and New York:
MACMILLAN AND CO.
1881

LONDON
R. CLAY, SONS, AND TAYLOR, PRINTERS
BREAD STREET HILL, E.C

INDEX

Abyssinia, Dr. Gerard Rohlf's journey in, 249
Academical Study, Biology as an, Prof. T. Jeffery Parker, 543, 573
Acton, Occurrence of Neolithic Implements at, Spencer G. Perceval 101, 260; Worthington G. Smith, 141
Acoustic Phenomenon noticed in a Crooke's Tube, C. R. Cross, 45
Acoustics, the Student's Handbook of, John Broadhouse, 580
Actineæ, Freshwater, Capt. W. Sedgwick, 189
Adams (Prof. W. Grylls, F.R.S.), Sound of the Aurora, 29
Æcidiomycetes, Spermogonia of, 592
Africa: Mittheilungen of the German African Society, 19; Pére Law's Expedition, 19; Dr. Holub's African Travels, 35, 58; the Sand Dunes of the Sahara, 67; F. C. Selous' Exploration of, 114; the Government of Uganda, 114; African Explora; tion, 149; Civilisation and Barbarism in South Africa, 227; the Baptist Congo Expedition, 250; to the Central Lakes and back, &c., J. Thomson, 353; Afrika im Lichte unserer Tage Bodengestalt und geologischer Bau, Josef Chavanne, 581; How I Crossed Africa, Major Serpa Pinto, 215
Agassiz (Prof. Alex.), Polydonia frondosa, 509
Agram, Earthquake Shock at, 202, 611
Albert Institute, Windsor, 87
Alford Weaver-Botanist, the, John Duncan, 6; Death of, 361
Algæ, Notes on, 169; On some New Lower Green, 292;
Algiers, French Association for the Advancement of Science at, G. F. Rodwell, 31
Algol, Minima of, 542
Allen (Grant), "Evolutionist at Large," 27; "Anglo Saxon Britain," 566
Allen (Capt. J. Allen), Singular Case of Shipwreck, 106; Luminous Phenomena on Rupture of Sea Ice, 459
Allman (Prof.), on the Development of the Ctenophora, 117
Alluvion, Sea-Shore, 286
Alpine Club, the Italian, 295
Alpine Congress, International, 246
Alpine Tunnel, Proposed New, 427
America: Proposed Meeting of the British Association in 1883, 16; American Naturalist, 45, 134, 158, 376, 479; American Journal of Science, 70, 134, 479, 600; American Meteorological Observations, W. B. Hazen, 189; American Cretaceous Flora, Prof. J. S. Newberry, 191; J. S. Gardner, 531; American Association for the Advancement of Science, Meeting of, at Cincinnati, Ohio, 146, 245; Prof. E. W. Claypole, 486; American Journalism, 265; American Degrees, 455 (*see also* United States, &c.
Anchor Ice, 301
Ancient Star positions, 520
Anderson (Wm.), the Hardening and Tempering of Steel, 21
Anderson (Tempest, M.D.), Prismatic Optometer, 618
Anemometer, a New Integrating, 467; Chas. E. Burton, 510, 582; H. S. Hele Shaw, 557
Anemometers, Whirled, Prof. G. G. Stokes, 250
"Anglo-Saxon Britain," Grant Allen, 566
Animal Instinct, Dr. W. B. Kesteven, 381
Animal Motion, Prof. J. Burdon-Sanderson, F.R.S., on Discoveries relating to, 439
Animal Life, Miscellanies of, Elizabeth Spooner, 566
Annalen der Physik und Chemie, 70, 134, 376, 400, 480, 600
Anthropology: Anthropological Institute, 47, 135, 232; Discovery of Implements near Thebes, 108; Transactions of the Washington Society of, 110; Anthropological and Anatomical Researches in Melanesia and Australia, Dr. Miklucho Maclay's, 157; "Anthropology," Edward B. Tylor, F.R.S., Alfred R. Wallace, 242; Meeting of German Anthropologists at Ratisbon, 426; Meeting of Austrian Anthropologists at Salzburg, 426
Ants, Sound-producing, Henry O. Forbes, 101; S. E. Peal, 484; Observations on the Habits of, Sir J. Lubbock, F.R.S., 142
Aquatic Hymenopterous Insect, Edwin Postock, 556
Arabia, Gleanings from the Desert of, Major R. D. Upton, Prof. W. Robertson Smith, 209
Archæology, Proposed American Institute of, 176
Archæological Discovery near Sewersk, Southern Russia, 541
Archæological Congress at Tiflis, 599
Archer (Surgeon-Major H.), Medusæ, 307
Archer (W., F.R.S.), Public Libraries, 386
Archives des Sciences Physiques et Naturelles, 94, 134, 278, 400, 600
Arctic (Dutch) Expedition, Zoology of the, 57
Arctic Echinodermata, P. Martin Duncan, F.R.S., and W. Percy Sladen, 97
Arctic Regions: the International Polar Commission, 113
Arctic Exploration: the *Polaris* Expedition, Dr. Emil Bessels, 194
Argentine Republic, Description Physique de la, d'après des observations personnelles et étrangères, par le Dr. H. Burmeister, 209
Argyll (Duke of), Struggle of Parts in the Organism, 581
Arlberg Tunnel, Boring of the, 291
Armstrong (Sir W., F.R.S.), Opening Address in Section G at the British Association Meeting, 448
Artificial Flight, Fred. W. Brearey, 466
Ascidians, Hypophysis in, 66, 591; Hypophysal Gland in, W. A. Herdman, 68
Ashton-under-Lyne Linnean Botanical Society, 566
Asia and Europe, Unexplored Parts of, 312
Astrolabe Gulf, 149
Astronomy: Astronomical Column, 18, 40, 65, 110, 177, 248, 277, 291, 342, 375, 425, 477, 520, 541, 591, 612; Astronomy for Amateurs, Cycle of Celestial Objects, Admiral W. H. Smyth, 234; Astronomical Congress at Strassburg, 246; Astronomische Nachrichten, 66
Athens Archæological Society, 341
Atkinson (Prof. R. W.), Brewing in Japan, 509
Atlantic Cable, New, Messrs. Siemens, 245
Atlas-Geography, A. H. Macdonell, 556
Atomic Theory, Prof. A. W. Williamson, F.R.S., on the Growth of, 413
Atoms, Dr. Henry Muirhead, 459
Atti della R. Accademia dei Lincei, 46, 134, 206, 278, 400
Atti della R. Accademia delle Scienze Fisiche e Matermatiche Napoli, 118
Aurora, Sound of the, 109; Dr. John W. Ogle, 5; Mrs. E. Hubbard, 5; Prof. W. Grylls Adams, F.R.S., 29; F. C. Constable, 53
Auroral and Magnetic Observations in High Latitudes, H. R. Procter, 241
Auroric Light, G. H. Kinahan, 142
Australia, Water in, F. J. Mott, 30
Australia and Melanesia, Anthropological and Anatomical Researches in, Dr. Miklucho Maclay's, 157
Australian Cycadaceous Stem at Kew Gardens, 425
Australian Aborigines: the Languages and Customs of several Tribes of Aborigines in the Western District of Victoria, Australia, James Dawson, Edw. B. Tylor, F.R.S., 529
Aveling (Edward B.), the Student's Darwin, Geo. J. Romanes, F.R.S., 429
Axolotl, Colour Change of, 388

Baer (Karl Ernst von), the Proposed Monument to, 108
Bakmut discovery of Rock Salt at, 541
Ball (John), the Florence Herbarium, 78
Ball (Prof. R. S., F.R.S.), the Distances of the Stars, 91
Ball (V.), Diamonds, Coal, and Gold of India, 579
Balloon Ascent by W. de Fonvielle, 225
Balloons: Double, Curious Experiment with, at La Villette Gasworks, Paris, 541, 566; Comets and, W. de Fonvielle, 381
Bangor, Maine, U.S., Earthquake at, 314
Banyuls-sur-Mer, New Zoological Station at, 610

Barbarism and Civilisation in South Africa, 227
Barfoed's (Dr. Chr. Th.) Lehrbuch der organischen qualitativen Analyse, 4
Barley Crops and Manures, 470
Barometer Pumps, James Johnstone, 79
Barometric Gradient and Wind, Rev. W. Clement Ley, 8
Barrett (Prof. W. F.), Mind-Reading *versus* Muscle-Reading, 212, 236
Bashforth (Rev. F.), Tide-Predicting Machines, 53
Bedford College, Education at, 131
Bees, Humble-, Bisected, T. Masheder, 335; Prof. Thos. McK. Hughes, F.R.S., 357; Edward Parfitt, 357
Belfast Naturalist Field Club, 40
Belgian Academy of Sciences, Prize programme for 1882, 147
Bell (Prof. Alexander Graham), Production of Sound by Radiant Energy, 42; upon a Modification of Wheatstone's Microphone and its Applicability to Radiophonic Researches, 302
Beltrame (Prof. G), Work on the Denka Language, 314
Bengal Asiatic Society, 88
Ben Nevis Observatory, 131, 201
Benzine, New Derivative of, 111
Berlin Geographical Society, 88; Zeitschrift, 364; Verhandlungen, 364
Bernays (Dr. Jakob), Death of, 148
"Berries and Heaths of Rannoch," 355
Berwickshire Naturalists' Club, 226
Bessels' (Dr. Emil) Account of the *Polaris* Expedition, H. N, Moseley, F.R.S., 194
Bettany (G. T.), First Lessons in Practical Botany, 235
Bible and Science, T. Lauder Brunton, F.R.S., Geo. J. Romanes, F.R.S., 332
Bibliography, Meteorological, A. Ramsay, 53
Biela's Comet in 1805, 178
Billing (Dr. Archibald, F.R.S.), the Death of, 455
Biology. Biological Notes, 66, 202, 292, 388, 591; Studies in Biology for New Zealand Students, F. W. Hutton, 188; Biological Station at Watson's Bay, 313; the Connection of the Biological Sciences with Medicine, Prof. T. H. Huxley, 342; Biology as an Academical Study, Prof. T. Jeffery Parker, 543, 573
Bird (Chas,), Short Sketch of the Geology of Yorkshire, Geological Map of Yorkshire, 458
Birds of Ceylon, Capt. Vincent Legge, 3; a List of European Birds, Henry E. Dresser; Birds Singing during Thunder, J. Shaw, 101; Birds suffering from Cold, J. V. Sládek, 165; British Museum Catalogue of Birds, 239; Migration of, W. G. D. Scott, 274; Birds of the Solomon Islands, 277; Descent of Birds, W. A. Forbes, 380
Birdwood (Dr. G. C. M.), Honour of Knighthood conferred on, 475
Birmingham Natural History Society, 40, 264
Birmingham Philosophical Society, 610
Birmingham (J.), Probably New and Variable Red Star, 164; Notes of the Cuckoo, 165; New Red Variable, 285; Jupiter, 285; the Comet, 308; Red Stars, 532
Bisected Humble-Bees, T. Masheder, 335; Prof. Thos. McK. Hughes, F.R.S., 357; Edward Parfitt, 357
Bishop (W. I.), *Re*, Thomson Whyte, 211; Dr. W. B. Carpenter, F.R.S., 188; and Dr. W. B. Carpenter, Geo. J. Romanes, F.R.S., 211
Blackwall (John), Death of, 86
Bleuler (E.), and K. Schmann, Zwangsmässige Lichtempfindungen durch Schall und verwandte Erscheinungen auf dem Gebiete der Anderen Sinnesempfindungen, 51
Blood of Insects, 388
Blyth (Edward), Natural History of the Cranes, 77
Boat, Curious, 567
Boddy (Evans Marlett), History of Salt, 123
Bodies, Buoyancy of, in Water, Dr. John Rae, F.R.S., 191; Dr. W. Curran, 166
Bolton's Microscopical Specimens, 147
Bombay Rainfall and Nile Floods, Morgan Brierley, 532
Bonney (Prof. T. G., F.R.S.), Geologist's Notes on the Royal Academy, 85; the Life, and Selections from the Correspondence of William Whewell, D.D., by Mrs. Stair Douglas, 147
Boutelle (Clarence M.), Optical Illusion, 191
"Book of the Beginnings," Gerald Massey, 49
Boracite, Experiments on, 112
Bordeaux, Phylloxera, Congress at, 565; Major General Maitland, 589
Boston (U.S.), Society of Natural History, 88
Botany: Text-Book of Indian Botany, Morphological, Physiological, and Systematic, W. H. Gregg, 188; Easy Lessons in Botany, according to the requirements of the Revised Code, 1880, 210; Popular Papers on the Phenomena of Plant Life, 210; First Lessons in Practical, G. T. Bettany, 235; Botany for Schools and Science Classes, W. J. Browne, 235; Practical Botany for Elementary Students, D. Houston, 283
Brain: a Journal of Neurology, 46
Brearey (Fred. W.), on Artificial Flight, 466
Brewing in Japan, Prof. R. W. Atkinson, 509
Brierley (Morgan), Bombay Rainfall and Nile Floods, 532
British Association: Meeting at York, 146; Proposed Meeting in America, 1883, 16; Preliminary Arrangements, 176, 385; Opening of, 431; the History and Work of the Association, 401; Inaugural Address of the President, Sir John Lubbock, D.C.L., LL.D., F.R.S., 402; New Officers, &c., 432; the Loan Collection of Scientific Apparatus, 432; Excursions, &c., 432: Grants, 433; the Foreign Visitors, 461, 492; Report of the Committee appointed for the Purpose of Investigating the Method of Determining the Specific Refraction of Solids from their Solutions, 462; Report of Committee on Meteoric Dust, 462; Report of Committee on Underground Water Supply, 462; Report on the Earthquakes of Japan, 462; Report of the Committee on Fossil Polyzoa, 463; Report of the Committee on Erratic Blocks. 463; Report on the Thermal Conductivity of Certain Rocks, 463; Report of the Committee on Tidal Observations in the English Channel and the North Sea, 487; Report of the Committee for Underground Temperature, 487; Report of Committee on Mathematical Tables, 488; Report of Committee for Investigation of Timor-lant, 488; Report of Committee on Natural History of Socotra, 488; Report on Caves and Kitchen-Middens at Cappagh, Co. Waterford, 488; Report on the Zoological Station at Naples, 488; Report of the Committee on Rudimentary Science Education, 488; Origin and Functions of the, E. W. Harcourt, 510
Section A (*Mathematical and Physical*).—Opening Address by the President, Sir William Thomson, F.R.S., 433; on the Possibility of the Existence of Intra-Mercurial Planets, by Prof. Balfour Stewart, F.R.S., 463; the Photographic Spectrum of Comet B 1881, by Dr. W. Huggins, F.R.S., 464; the Electrical Discharge through Colza Oil, Dr. A. Macfarlane, 465; on the Electric Conductivity and Dichroic Absorption of Tourmaline, Prof. Silvanus Thompson, 465 on the Application of Electricity to the Localisation of a Bullet in a Wound, W. H. Preece, 465; on the General Coincident between Sun-Spot Activity and Terrestrial Magnetic Disturbance, Rev. T. Howlett, 465; on Artificial Flight, by Frederick W. Brearey, 466; on the Arrestation of Infusorial Life, by Prof. Tyndall, F.R.S., 466; the Sun-Spot Period and Planetary Tides in the Solar Atmosphere, by F. B. Edmonds. 466; on a New Integrating Anemometer, by H, S. Hele Shaw and Dr. Wilson, 467; on a Universal Sunshine Recorder, by G. M. Whipple, 467; on the Calibration of Mercurial Thermometers by Bessel's method, by Prof. Rucker, 467; on the Economy of Metal in Conductors of Electricity, by Sir William Thomson, F.R.S., 489; Illuminating Powers of Incandescent Vacuum Lamps with Measured Potentials and Measured Currents, Sir William Thomson and J. T. Bottomley, 490; an Analysis of Relationships, Dr. A. Macfarlane, 491; on a Microscope with Arrangements for Illuminating the Sub-Stage, by E. Crossley, 491; Observations of Atmospheric Electricity at Kew Observatory during 1880, G. M. Whipple, 491; on Prof. Phillips' Rainfall Observations made upon York Minster, G. J. Symons, F.R.S., 491; on some of Bell and Tainter's Recent Researches and their Consequences, W. Lant Carpenter, 491; on Magnetic Disturbances, Prof. W. G. Adams, F.R.S., 492
Section B (*Chemical Science*).—Opening Address by the President, Prof. A. W. Williamson, F.R.S., 413; on a Process for Utilising Waste Products and Economising Fuel in the Extraction of Copper, J. Dixon, 467; on the Chemical Action between Solids, Prof. Thorpe, F.R.S., 467; Metallic Compounds containing Bivalent Hydrocarbon Radicals, J. Sakurai, 467; on the Siliceous and other Hot Springs in the Volcanic District of New Zealand, W. Lant Carpenter, 467; Note on the Chrome Iron Ore of Japan, Dr. Divers, 468; on the Oxides of Manganese, V. H. Veley, 468; on the Inferences deducible from High Molecular Weights as

exhibited by the Oxides of Manganese, Prof. Odling, F.R.S., 468; on Peppermint Camphor, R. W. Atkinson and H. Yoshida, 468; on the Occurrence of Selenium and Tellurium in Japan, Dr. Divers, 468; on the Sodium Alum of Japan, Dr. Divers, 468; Brewing in Japan, R. W. Atkinson, 468; on the Specific Refraction and Dispersion of Light by Liquids, by Dr. J. H. Gladstone, F.R.S., 468; on the Production of Crystals by the Action of Metals on Carbon Disulphide in Closed Tubes, P. Braham, 468; on the Alleged Decomposition of the Elements, Prof. Dewar, F.R.S., 468; on Manganese Nodules, J. Y. Buchanan, 469; on the Action of Zinc, Magnesium, and Iron on Acidified Solutions of Ferric Sulphate, Prof. T. E. Thorpe, F.R.S., 469; on the Reducing Action of Zinc and Magnesium on Vanadium Solutions, Prof. H. E. Roscoe, F.R.S., 469; on a New Method of Measuring certain Chemical Affinities, A. Tribe, 469; on some Phenomena of the Nature of Chemico-Magnetic Action, W. Thomson, 469; on the Double Iodide of Copper and Mercury, Prof. S. P. Thompson, 469; Alterations of the Properties of Nitric Ferments by Cultivation, R. Warington, 470; on the Fluid Densities of certain Metals, Prof. W. C. Roberts, F.R.S., and T. Wrightson, 470; on Molecular Attraction, F. D. Brown, 470; on the Relative Atomic Weights of Silver, Manganese, and Oxygen, by Prof. Dewar and A. Scott, 470; on the Phosphates of Lime and Ammonia, J. A. Wanklyn, 470; on the Separation of Hydrocarbon Oil from Fat Oils, A. H. Allen, 470; on Bowkett's New Thermography, W. Lant Carpenter, 470; Blowing-Wells near Northallerton, T. Fairley, 473; on the New Metal Actinium, J. S. Phipson, 470; on some Vapour-Density Determinations, Prof. Dewar and A. Scott, 470; on Experiments with Manures on Barley Crops, Ivison Macadam, 470; the Present State of Chemical Nomenclature, Prof. A. W. Williamson, F.R.S., 492; Cellulose and Coal, C. F. Cross and E. J. Bevan, 493; Hydration of Salts and Acids, C. F. Cross, 494; on Colliery Explosions, W. Galloway, 493

Section C (*Geology*).—Opening Address by the President, Dr. A. C. Ramsay, F.R.S., 419; on the Laurentian Beds of Donegal and of other Parts of Ireland, Prof. Edward Hull, F.R.S., 471; Laurentian Rocks in Ireland, G. H. Kinahan, 471, 591; on the Occurrence of Granite *in situ* about Twenty Miles South-West of Eddystone, A. R. Hunt, 471; on the Causes of Volcanic Action, Prof. J. Prestwich, F.R.S., 471; the Connection between the Intrusion of Volcanic Action, Prof. W. J. Sollas, 472; a Restoration of the Skeleton of Archæopteryx, with some Remarks on Differences between the Berlin and London Specimens, Prof. H. G. Seeley, F.R.S., 472; on *Simosaurus pusillus* (Fraas), a Step in the Evolution of the Pleseosauria, Prof. H. G. Seeley, F.R.S., 472; Influence of Barometric Pressure on the Discharge of Water from Springs, Baldwin Latham, 472; on some Points in the Morphology of the Rhabdophora, John Hopkinson, 472; the Glacial Deposits of West Cumberland, J. D. Kendall, 473; on "Flots," J. R. Dakyns, 473; on the Lower Cambrian of Anglesea, Prof. J. McK. Hughes, 473; on the Knarled Series of Amloch and Holyhead in Anglesea, Prof. J. McK. Hughes, 473; Notes on the Subsidences above the Permian Limestone between Hartlepool and Ripon, A. G. Cameron, 473; the Great Plains of Northern India not an Old Sea Basin, W. T. Blanford, F.R.S., 473; the Gold Fields and Quartz Outcrops of Southern India, William King, 473; Geology of the Island of Cyprus, R. Russell, 473; on some Sections in the Lower Palæozoic Rocks of the Craven District, J. E. Marr, 473; Life in Irish and other Laurentian Rocks, C. Moore, 473; the Subject Matter of Geology and its Classification, Prof. W. J. Sollas, 474; Exploration of a Fissure in the Mountain Limestone at Raygill, James W. Davis, 474; on the Zoological Position of the Genus Petalo-rynchus, J. W. Davis, 474; on the Microscopic Structure of Coal from East Scotland and South Wales, Prof. Williamson, F.R.S., 474; on an International Scale of Colour for Geological Maps, W. Topley, 474; on the Rhætics of Notts, E. Wilson, 474; Notes on the Cheshire Salt Fields, C. E. De Rance, 474; on the Strata between the Chillesford Beds and the Lower Boulder Clay, Prof. Prestwich, 474; on the Upper Bagshot Sands of Hordwell Cliff, Hampshire, E. B. Tawney, 475; a Preliminary Account of the Working of Dowkerbottom Cave in Craven during August, 1881, E. B. Poulton, 494; on Asteromilia Readi, a New Species of Coral from the Oligocene of Brockenhurst, Prof. Martin Duncan, F.R.S., 495; on the Formation of Coal, E. Wethered, 495; on the Palæozoic Rocks of North Devon and West Somerset, W. A. E. Ugsher, 495; on the Characters of the "Lansdown Encrinite" (*Millericrinus Pratti*), P. Herbert Carpenter, 495; on the Two Types of Cambrian Beds of the British Isles, Prof. E. Hull, F.R.S., 496; on a discovery of Fossil Fishes in the New Red Sandstone of Nottingham, E. Wilson, 496; Glacial Sections at York and their Relations to the later Deposits, J. E. Clarke, 496; the Devonio-Silurian Formation, Prof. E. Hull, F.R.S., 496; the Glacial Geology of Central Wales, Walter Keeping, 498; on the Lower Kueper Sandstone of Cheshire, A. Strachan, 498

Section D (*Biology*).—Opening Address by the President, Prof. Richard Owen, C.B., F.R.S., 421

Department of Anthropology.—Opening Address by Prof. H. Flower, F.R.S., 436; Geographical Distribution of Mankind, Miss A. W. Buckland, 500; the Papuans and the Polynesians, Staniland Wake, 500; Excavations in the Earthwork called Ambresbury Bank in Epping Forest, Gen. Pitt-Rivers, 500; on the Stature of the Inhabitants of Hungary, Dr. Beddoe, 500; on the Physical Characters and Proportions of the Zulus, Mr. Bloxam, 500; on the Animism of the Indians of British Guiana, E. F. im Thurn, 500

Department of Anatomy and Physiology.—Opening Address by Prof. J. Burdon-Sanderson, LL.D., F.R.S., 439; on the Conario-hypophysial Tract, or the Pineal and Pituitary Glands, by Prof. Owen, C.B., F.R.S., 498; on the Development of Colour Sense, Dr. Montague Lubbock, 499; Function of the Two Ears in the Perception of Space, Prof. S. P. Thompson, 499; on the Incubation of the Indian Python, W. H. Forbes, 499; on the Structure and Homologies of the Suspensory Ligament of the Fetlock in the Horse, Ass, Ox, Sheep, and Camel, Dr. D. J. Cunningham, 500, 521

Department of Zoology and Botany.—On the Sense of Colour in Animals, Sir John Lubbock, F.R.S., 500; on the mode in which the Seed of Stipa buries itself in the Ground, Sir John Lubbock, F.R.S., 501; on the Constancy of Insects in visiting Flowers, A. W. Bennett, 501; on Jurassic Birds and their Allies, Prof. O. C. Marsh, 501; on the Anatomy and Classification of the Petrel, W. A. Forbes, 501

Section F (*Geography*).—Opening Address on Geographical Distribution by Sir J. D. Hooker, F.R.S., 443

Section G (*Mechanical Science*).—Opening Address by Sir W. Armstrong, D.C.L., F.R.S., 449

British Medical Association, 290

British Museum, the Geographical Department of, 178; Catalogue of Birds, 239

British Mosses and Hepatics, London Catalogue of, 211

Broadhouse (John), the Students' Handbook of Acoustics, 580

Broca (Dr.), Monument to the Memory of, 108

Brown (Robert), Countries of the World, 306

Browne (Walter R.), on the Relative Value of Tidal and Upland Rivers, Estuaries, and Harbours, at the Institute of Civil Engineers, 17

Browne (W. J.), Botany for Schools and Science Classes, 235

Brownell (J. T.), Wasps, 484

Bruhns (Prof.), Death of, 290

Brunton (T. Lauder, F.R.S.), "Bible and Science," Geo. J. Romanes, F.R.S., 332

Brutel de la Rivière (C. J. E.), Hot Ice, 4

Buchan (Alexander), Weather and Health of London, 143, 173

Bulletin of the United States Geological and Geographical Survey of the Territories, 45

Bulletin de l'Academie Royale des Sciences de Belgique, 94, 278, 400, 480, 600

Bulletin de l'Academie Imperial des Sciences de St. Petersbourg, 94

Bunsen-Pump, the So-called, Dr. H. Sprengel, 53

Buoyancy of Bodies in Water, Dr. W. Curran, 166; Dr, John Rae, F.R.S., 191

Burnham Beeches, 87

Burmeister (Dr. H.), Description Physique de la Republique Argentine d'après des Observations personelles et Etrangères, 209

Burton (Chas. E.), the Comet, 221; Integrating Anemometer 510, 582

Butterflies of Europe, Henry Chas. Lang, M.D., 177, 283
Buxton Thermal Spring, Analyses of the Mud deposited round the, 542

Calabar Bean as a Preservative, Dr. E. MacDowel Cosgrave, 583
Calorimeter, a Simple Form of, 41
Cambridge: Annual Report on the Museums, 93; Observatory Report, 158
Canadian Naturalist, 133
Cantor Lectures, 40
Caoutchouc, Electric Expansion in, 180
Cape, Thunder Storm at the, C. Tomlinson, 166
Capper (Thomas), Six-Fingered Family, 166

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH

THURSDAY, MAY 5, 1881

EVOLUTION

Evolution, Expression, and Sensation. By John Cleland, M.D., F.R.S., Professor of Anatomy in the University of Glasgow. (Glasgow: James Maclehose, 1881.)

PROF. CLELAND is so well known as a skilled anatomist who holds some views of his own on the subject of evolution, that we are glad to welcome in this book a definite statement of what these views are. The work, moreover, is throughout very interesting. It is a collection of six essays, of which the first is on Evolution, the second on Expression, the third on Vision, the fourth on a Theory concerning the relations of Body and Mind, the fifth on Theories of the Cell, and the sixth a reprint of an address to medical students on Truth, Pathology, and the Public. These essays display a good deal of original and suggestive thinking, though not always of a kind with which we are disposed to agree.

The first essay, on the "Evolution of Organisations," expresses the view that gradual development has been the law of organic nature, but that this law has always been subservient to, or expressive of, supernatural design. After some introductory paragraphs the author clearly enough strikes his key-note thus. The fact of evolution being granted, it "may be conceived of variously, both in respect of character and cause. In its character it may be conceived of as a growth without aim, forming altogether an indefinite aggregation like the sum of the branches of a tree; or the view may be held that it is an orderly arrangement, like some vast temple in which every minaret and most fantastic ornament has got its own appointed place and harmonies, while the central tower ascends to its pre-ordained completeness." He then goes on to complain that "the name of Evolutionist has, with curious obliviousness, been assumed as a distinctive title by those who believe that the evolution is merely indefinite. . . . Had they called themselves Demolitionists, on account of their disbelief in morphological design, the name might possibly have been more expressive."

From this quotation the tone of the whole essay may be inferred. The essay, however, is written in the most temperate style, and by a man who certainly has a good right to be heard on all matters pertaining to morphology. We shall therefore offer a few remarks upon his general position as indicated by the above extract.

As regards the mere name appropriated by evolutionists of the naturalistic school, we cannot see that there is much ground for complaint. It is intended to signify belief in gradual development by natural causes as distinguished from sudden changes due to supernatural intervention. The name therefore has really no direct reference to any ulterior belief or opinion as to whether behind the natural causes producing evolution there is any supernatural design—provided only that this design is not supposed to display itself by breaking out into miracle, or interference with these natural causes. Therefore Prof. Cleland has quite as much right as Prof. Häckel, whom he rightly enough regards as a representative of the thorough-going "Demolitionists," to call himself an evolutionist, and we do not see that Häckel could properly deny him this right; they both believe in evolution as a process, much as they may differ in their views on all that lies behind that process. And the only reason why the term evolutionist has in many minds become identified with extra-theistic opinion, is simply because the theory of evolution has been for the most part developed by minds unfettered by any preconceived ideas on "the Method of Divine Government." If we had had to wait for the natural theologians to teach us the theory in question, Prof. Cleland's essay would not yet have been conceived. It nevertheless remains perfectly true that now when it has been conceived, written, and printed, he is as much an evolutionist as anybody else.

But when we pass from this question of mere terminology to the more important matter with which the essay is concerned, we are brought face to face with a question which it is useless in these columns to discuss. This question is whether the new light which science has shed on biology by the theory of descent is compatible with the older theory of design, and if so, to what extent. It is useless in these columns to discuss this question, because it is one upon which opinions differ, and may legitimately differ, through all points of the intellectual compass; there being here no general medium of knowledge to direct opinion, every man's judgment rests in whatever

position it may be brought to rest by the particular circumstances of his temperament and education. Thus it is that to Prof. Cleland it appears most reasonable to conclude that "in the evolutions of organisation there is a non-material impulse," to which virtually we may refer all difficulties that we cannot solve in our contemplation of the natural process; while to Mr. Darwin this method of relegating any special question in science to an ultimate theory of things amounts simply to "a re-statement of the question." As a question of science no explanation is furnished by this method, and whether or not in particular cases any such explanation is possible, men of science, *as such*, must never assume, as by following the method in question they would assume, that such explanation is impossible.

Therefore, so long as men of science are watchfully careful never, as Prof. Cleland phrases it, "to make final do the duty of efficient causes," so long it matters not to science what views her individual cultivators may hold on super-scientific questions. Only it is certain that a man strongly imbued with belief in final causes is apt to incur the danger of confusing them with efficient causes, and a striking instance of this fact is displayed by Prof. Cleland himself, where he says, "If evolutions are definite, or, in other words, if morphological designs exist, the necessity for explaining *all* affinity by genetic relationship disappears." This we understand to mean that wherever affinity cannot at once be seen due to "efficient causes," we are at liberty forthwith to ascribe it to "final causes." And this presents in as bad a form as ever the doctrine which for centuries has paralysed the movements of science. If a scientific man of to-day wishes to retain his belief in "morphological design," it must be as a belief in some wholly transcendental principle with which science has nothing whatever to do. Otherwise he fails in scientific method, as for instance Prof. Cleland fails where he points to "sex and symmetry" as due to design, only because he does not see how they can be due to natural selection. It makes not an atom of difference to the logical position of science whether or not the fact of sex or symmetry, or any other fact to which any writer can point, is inexplicable by natural selection. The logical position of science is that if such facts are not due to natural selection, they must be due to some other natural causes which we may reasonably hope some day to *ascertain*. And if it is asked what is the justification of this logical position to which science has been raised, the answer is supplied by the history of science itself. Let any one go through the writings of Paley, Bell, or Chalmers, and strike out all the instances of "morphological design" which he plainly sees can now be explained by natural selection, and he must be a very dull man if he continues to repose any confidence in the residue as evidence of causes other than strictly natural. In the face of so immense an analogy the burden of proof lies with the teleologists to show that any special cases to which they may point as still requiring explanation are to be regarded as inexplicable; and this burden most assuredly is not discharged by Prof. Cleland when he seeks to strike at the heart of natural selection as a natural cause by saying of heredity that in it he "can only recognise a phenomenon the origin of which demands an explanation." No doubt this explanation is demanded but is demanded at the hands of observation and experiment—not from the cloudlands of "spirit which pervades the whole."

We have thought it well to devote the main part of this review to the essay on Evolution, because the occasion seems a suitable one to raise our voice against the pernicious habit of flirting with final causes which still lingers among a certain section of scientific workers. Let any one who so may wish continue to believe in final causes; but if he does not also wish to clog the wheels of science, let him cease to throw his final causes into any gap which the roads of inquiry may present. Science, as such, requires no *deus ex machinâ*, and those of her votaries who feel that *they* require him will best consult her interests by laying the strongest possible emphasis upon the *ex*.

The most interesting of the other essays is that on Expression. In a section devoted to "Permanent Expression," it is observed that while in many respects the physical peculiarities of permanent expression admit of being explained by obvious causes, in other respects this is not so. Thus, for instance, "a massive chin is so distinctly a physiognomic representation of firmness, that an artist would in vain attempt to exhibit the resolution of a Cromwell in a face with a small and narrow jaw, or with one of those pretty chins like a bagatelle ball, not uncommon in certain localities. . . . Yet the chin has no physical function whatever, so far as I am aware."

In a section on the "Expression of the Emotions," Dr. Cleland argues in favour of an active principle which may be defined as unconscious symbolism, and certainly in the course of a few interesting and suggestive pages he makes out a strong case. It is first shown that language serves, as it were, to stereotype a number of symbolic ideas, so that, for instance, words signifying elevation come also to signify greatness, goodness, &c., while we likewise "associate impressions derived through the organs of sense with impressions from the moral world similarly pleasant or otherwise, as in the case of sweetness, bitterness, brightness, and gloom." Such associations having become firmly established, the way is prepared for their expression by gesture; so that at last "the workings of the mind are expressed by attitudes, gestures, and movements of body of a nature correlative with them." Thus "slight movements of the arms express the hugging of an idea to the bosom when nothing but what is thoroughly impersonal is thought of, and the fingers bend as if to keep a something in the hand when nothing but delightful sentiment is conceived." And similarly the gesture of sweeping away, backwards, and downwards a repulsive object from before the eyes, "is a gesture applied to the intangible and invisible; by it the cleric puts away false doctrine, and the fastidious sublimely brands a notion as vulgar."

This theory, of which many other illustrations are given, is to some extent the same as that which Mr. Darwin calls "serviceable associated habits," seeing that the principle of association is concerned in both; but as in Dr. Cleland's theory the association need not be "serviceable," and as it is concerned with an unconsciously symbolic representation of ideas, we think with him that it deserves to be considered as a distinct theory, and we can scarcely doubt that the principle with which it is

concerned has played an important part in the development of emotional expression in man.

The remaining essays, which we have no further space to consider, are likewise entertaining, and we therefore recommend the book to all who are interested in the sundry biological theories of which it treats.

GEORGE J. ROMANES

LEGGE'S "BIRDS OF CEYLON"

A History of the Birds of Ceylon. By Capt. Vincent Legge, R.A. Part III., concluding the Work. 4to. (London: Published by the Author, 1880.)

THE ornithologists are certainly active at the present time. We have just recorded the commencement of an important work on the Birds of New Guinea, we have now to notice the conclusion of an excellent volume on the Birds of Ceylon. Capt. Legge's book will, we are sure, be much valued by the numerous European residents in the coffee-districts of the island, who cannot fail to have their attention attracted by the beautiful forms of ornithic life which surround them, and as yet have had no ready means of becoming acquainted with what is known of them. Jerdon, singularly enough, did not include Ceylon in the area of his "Birds of India," and although Blyth, Layard, and Holdsworth have worked long and laboriously on the Ceylonese avifauna, their memoirs on the subject are dispersed about in various serials and other publications, which it is not possible for a coffee-planter to have at his command. A general *résumé* of the Ceylonese ornithology, with full descriptions of all the species, with excellent illustrations of the peculiar forms, and with every necessary detail required for the instruction of the local student and collector, is therefore likely to be a most acceptable piece of work to the resident in the island. At the same time Capt. Legge has produced an elaborate and scientifically exact Monograph of a local Avifauna, which will be received with welcome by naturalists of every class, and is well worthy to take its place on their shelves alongside such works as Dresser's "Birds of Europe" and Buller's "Birds of New Zealand," with which it corresponds in size and character.

As regards the general features of the Ceylonese Ornis Capt. Legge observes that the island, "although it contains none of those remarkable forms which characterise the birds of some of the Malay islands, undoubtedly possesses a rich avifauna; and, considering its geographical area (about five-sixths of Ireland), the number of species is very large. The tropical position of Ceylon, coupled with its location in the path of the monsoon winds and rains, fosters the growth of luxuriant vegetation and verdant forests, which, as a matter of course, teem with all that wonderful insect-life necessary for the sustenance of birds. Hence the large number of resident species inhabiting it; whilst the fact of its being situated at the extreme south of an immense peninsula makes it the finishing point of the stream of waders and water-birds which annually pass down the coast of India. Lastly, the prevalence of a northerly wind at the time of migration of weak-flying warblers brings these little birds in numbers to its shores."

The total number of species of birds included in Capt. Legge's work is 371, of which two have been introduced by man's agency, and about eighteen others are somewhat doubtful. The authentically determined birds of Ceylon may therefore be stated at about 350, of which forty-seven are peculiar to the island; this indicates a very large amount of individuality. The relationship of the Ceylonese Ornis, Capt. Legge tells us, is, as might have been expected from the geographical position of the island and its separation from the mainland merely by a shallow strait, "closer to that of South India than to the avifauna of any other part of the peninsula. Wallace, in his great work on the 'Distribution of Animals,' considers the island of Ceylon and the entire south of India as far north as the Deccan as forming a subdivision of the great 'Oriental Region.' It is however in the hills of the two districts, which possess the important element of a similar rainfall, where we find the nearest affinities both as regards birds and mammals; and this is exemplified by the fact of some of the members of the Brachypodidæ and Turdidæ (families well represented in both districts) being the same in the Nilghiris and in the mountains of Ceylon, while many of the Timaliidæ and Turdidæ in one region have near allies in the other.

"But though this strong similarity in the avifauna of the mountains in question, as well as their geographical characters, indicate a contemporaneous upheaval and enrichment with animal life of their surfaces, a similar connection is found between the northern parts of the island and the low country of the Carnatic.

"Here, again, we have in the fossiliferous limestones of the two regions an undoubted connection, and also an affinity in their avifaunas, which differ totally from that of the mountain-districts on either side of the straits."

In concluding our notice of this admirable volume we must not fail to call special attention to the plates which have been drawn by Mr. Keulemans, and are excellently coloured. They are devoted to the illustration of the species peculiar to Ceylon. Nor must we forget the map, which forms the frontispiece and shows the five zoo-geographical regions into which the author divides the island, besides the various localities referred to in the course of the work.

OUR BOOK SHELF

A Manual of Ancient Geography. Authorised Translation from the German of H. Kiepert, Ph.D. (London: Macmillan and Co., 1881.)

THE name of Kiepert is in itself a sufficient guarantee of the thoroughness and accuracy of a book on geography. That writer, in his "Lehrbuch der Alten Geographie"—from which the present work is abridged, though he himself describes the "Lehrbuch" as a "Werkchen"—has brought together a vast amount of well-digested information respecting ancient geography, so that the book excites the student's admiration from the grasp it displays of the many sides—geological, ethnographical, philological, historical, climatological, &c.—of that wide-reaching subject, and the discernment and critical spirit which characterise it. To the English reader the smaller work, which has been excellently translated by G. A. M., supplies a want that has long been felt. We possess no satisfactory book on the subject intermediate between primers and elaborate treatises, and the present one has all the advantage of being the condensation of a larger book, so that in reading it we feel all through that the

author draws on a wide field of knowledge. What is most needed in such a manual is that it should be clear, interesting, suggestive, and not overladen with such details as clog the memory while they make no permanent impression on the mind. In the present work the statistical form is avoided, and the dry bones of geography are clothed with such information as gives them life and colour. The vegetation and products of the different countries, their inhabitants and history, are all noticed in connection with the configuration of the ground. Thus of Italy we are told that, "besides the oak forests which covered the lower slopes, and the beeches and firs which covered the higher parts of the mountains up to 5000 feet, and far more densely in ancient times than now, a large part of the mountain region, especially of the Apennines, owing to the steep and rocky character of the ground, remains unsuited for any other purpose but cattle-feeding, and this in the higher regions is confined, as in the Alps, to the summer months. A regular interchange of cattle and sheep according to the seasons, such as is now usual, already went on in antiquity, as, for instance, between Samnium and Apulia." So too, when the volcanic system of Italy is mentioned, we are told that "the lava flowing from these volcanoes afforded in old Roman times, as it does still, the hardest material for binding together the great military roads (*silex*), while the conglomerate of tufa, consisting of the lighter masses thrown down, which was spread over the plain, was the commonest material for building, and its weather-worn surface made the most fertile soil for tillage." In a similar geological sketch of Greece, the various centres of volcanic action are noticed, and the metals which are found in different parts of the country. In respect of the history and politics of the several districts a large amount of useful information is brought together. For instance, we find a clear statement of the names by which the ancient Greeks were known at different times and by different peoples, and the history of the name Italia is discussed in the same manner. Nor are outlying nations neglected. Under the headings "The Scythians" and "The Sarmatae" we get the results of a large amount of research and discussion, and the Carthaginian province in Sicily is duly noticed. Philology again, which is now no unimportant handmaid of geography, is made to add its contribution of information; as when we are told that the names Asia and Europe "are derived from the *açu* and *irib* of the lately-deciphered Assyrian monuments, meaning east and west, and answering to the Homeric expression *πρὸς ἠῶ ἠελιόντε* and *πρὸς ζόφον*, to the later Greek names of countries, Ἀνατολή and Ἑσπερία, to the modern *Orient* and *Occident* (borrowed from the Latin), or to the Italian *Levante* and *Ponente*." Sometimes a name is connected with the features of the ground, as where the Jordan, with its steep descent down a deep valley, is explained to mean "the down-flowing"; or where Zancle is said to be called "the Sickle" from "the form of the tongue of land which incloses the natural harbour." So, too, the student is incited to further research when he learns that Mount Atabyrion in Rhodes bears in reality the same name as Mount Tabor, and that other Greek names have undoubtedly Semitic appellations; and his appetite for history is whetted by discovering that Cappadocia is the Old Persian *Katpatuka*, and that Marsala is the mediæval Arabian name for Lilybæum. Numerous points like these are illustrated by geography, and M. Kiepert gives his readers the full benefit of them. But this is not to the neglect of the more substantial part of the subject, which is amply and clearly expounded. H. F. TOZER

Lehrbuch der organischen qualitativen Analyse. Von Dr. Chr. Th. Barfoed. Dritte Lieferung. (Kopenhagen: Andr. Ferd. Höst und Sohn, 1881.)

DR. BARFOED'S work on organic qualitative analysis is completed by the issue of the present part. The author is to be congratulated on producing so valuable a book of reference for the laboratory worker. The present part contains a full account of the tests for the commoner alkaloids, and for a few of the more fully examined vegetable colouring matters. A general method for the examination of organic substances, whether free from, or mixed with, inorganic compounds, is also given. This general plan is not however arranged in cut-and-dry tabular form, but is rather a guide which in the hands of the experienced student will prove of much value. We can but repeat what we said in noticing the first part of this book, that every student who is desirous of obtaining a real knowledge of qualitative organic analysis, ought to possess Dr. Barfoed's work.

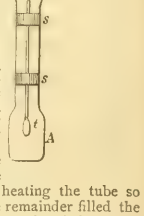
LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Hot Ice

THAT the experiments of Dr. Carnelley on hot ice have excited much interest is not to be wondered at. His statement, however, that ice could be raised to a temperature of 180° without melting was so amazing that many a one could not accept it without repeating the experiments. Soon after the first short notice of Dr. Carnelley appeared in NATURE we took up the matter, but as the method used by Dr. Carnelley seemed to us to be somewhat troublesome, we made use of quite a different method. In the axis of a glass tube AB, 16 mm. in diameter, and 56 c.m. in length was fixed a thermometer *t* by means of two strips *ss* of elastic brass sheet. One of the ends of the tube was 22 mm. in diameter, while the other end had the shape of a bulb, and was drawn out in a narrow tube, *a b*, about 50 c.m. in length. The tube was placed in an inclined position with the end *b* in a glass filled with water that was kept boiling. The bottom of the glass was covered with a layer of mercury. Next the tube was heated by a Bunsen burner; a part of the air was driven out, and, after retiring the burner, the tube was partly filled with the boiling water of the glass. The water in the tube was then boiled, a still greater part of the air escaped, and by removing the burner the tube filled itself nearly entirely. The heating and cooling were repeated three or four times, and in this manner the tube could be filled with the boiling water, not a single air-bubble being left. The end *b* of the narrow tube was now dipped in the mercury, and by heating the tube so much of the water was driven out that the remainder filled the enlarged part A for three-fourths. The tube being now slowly cooled, the mercury rose in the tube *a b*, and it was very easy to seal the tube at *a* with the blowpipe. The water in A was now frozen, and by gently warming with the hand the ice-cylinder was loosened from the tube; by inverting the tube the molten ice was brought into the bulb B, where it was fixed by freezing. This part of the process presents some difficulty. When the heating by the hand was not stopped in time, too much of the ice was converted into water. However, by placing the bulb B in a freezing mixture of snow and salt the melting can be almost instantly arrested. The bulb of the thermometer being in this way surrounded with an ice-cylinder 12 mm. in diameter, the bulb B had only to be placed in the freezing mixture to have the apparatus ready for the appliance of heat. The results of our experiments confirm those of Dr. Carnelley, inasmuch as the ice did not melt, notwithstanding the heating of the tube at A was in one instance so strong that the glass was softened and gave way to the external pressure of the air. They differ, however, as regards the temperature of the ice, which remained generally at $-7°$. By very strong heating



the thermometer rose to 0°, but *never exceeded that point;* when not, the bulb of the thermometer, by the volatilising of the ice, was partly laid bare. As it appears by the detailed description of Dr. Carnelley's experiments in NATURE, vol. xxiii. p. 341, that the success depends for a great part on the size of the condenser, we have made another apparatus with a condenser of half a litre; the results we may obtain therewith will be related shortly.

We have also made some experiments on naphthalene. The pressure of the naphthalene vapour at the melting-point, nearly 80°, being ± 9 mm., as was found by a preliminary proof, it was expected that it would not be very difficult to obtain and to maintain a vacuum sufficient to observe the demeanour of naphthalene under similar circumstances as ice. The apparatus we used resembles in its principal features that we made use of in experimenting on ice; alone, the condensing surface was much greater. The thermometer bulb being imbedded in a cylinder of pure naphthalene 13 mm. in diameter, the thermometer was fixed in the axis of the glass tube, and this latter drawn out. A small quantity of water being brought in the tube, the pressure was reduced by means of an ordinary air-pump to 5 mm., and the drawn-out end of the tube melted through. In another instance the tube was several times filled with carefully-dried carbonic acid and exhausted, and lastly, when the pressure had been reduced to 7 mm., sealed. To remove the remaining carbonic acid and aqueous vapour a certain quantity of caustic potash and some pieces of oxide of calcium were inclosed in the tube. In what manner the tube had been prepared, the results when heat was applied, the upper part of the tube being cooled in a freezing-mixture or simply in snow, were always the same. The thermometer rose very rapidly to about 79°, and *stayed at that point* as long as no part of the thermometer bulb was denuded of naphthalene. At the same time the naphthalene sublimed very regularly, covering the sides of the tube next to the heated part with a beautiful layer of naphthalene crystals.

Sound of the Aurora

THE interesting communications which have lately appeared in your periodical regarding the supposed connection between "sound" and the "aurora" (NATURE, vol. xxiii. pp. 484, 529, 556), lead me to suppose that the following notes may be considered by you and your readers worthy of record. They were copied last autumn by myself from the Strangers' or Visitors' Book at the Hotel on the Æggischorn, and bore the date July 10, 1863:—

"Visit to the Col de la Jungfrau described: On descent surrounded by thunderclouds evidently charged with electricity. At 12.15 a sound similar to that made by a boiling kettle was heard to issue from one of the alpenstocks, and very soon a similar sound issued from all the bâtons. On shaking the hands similar sounds issued from the fingers. Observing that the veil of one of the party stood upright on his hat, one of the gentlemen and one of the guides, who had experienced prickly sensations on the crown of the head, removed their hats, when their hair stood up as if under a powerful electrical machine. Whenever there was a peal of thunder all of the phenomena ceased, to be speedily renewed when the peal was over. At such times all the members of the party felt severe shocks in the parts of the body which were most affected; and one gentleman had his right arm paralysed and rendered useless for several minutes. The clouds passed away and the phenomena finally ceased at 12.30. The guides with us were Joseph Marie Claret of Chamouni, and Smith of this house, and they were as much affected by the electricity as we were. At the top of the Col the aneroid barometer stood at 18·83."

I believe the above statement, clear and pointed as it is, was signed by the names of Watson, Sowerby, and Adams.

It will be seen that other phenomena are mentioned, in addition to the sounds heard in connection with the electrical ones, which are worthy of regard. I would, among other points, draw attention to the effect produced on the arm of one of the travellers, and should be glad to know from any of your correspondents whether they have met with other like results of electrical interference with the actions of muscles in mountain travelling.

I may mention in passing that in the same Visitors' Book at the Æggischorn Inn I found notes to the effect that the Jungfrau and the Aletschorn were first ascended by a lady in August of the year 1863. JOHN W. OGLE

30, Cavendish Square, W.

A PRESUMPTION as to the true character of the sound of the aurora is perhaps offered by the fact that to many persons a flash of lightning is accompanied by a distinct *whishing* sound. As this is simultaneous with the flash, and therefore evidently subjective, it seems to offer evidence merely of the close connection existing between the senses of seeing and hearing.

April 30 E. HUBBARD

Symbolical Logic

IN my recent letter on Symbolical Logic (see NATURE, vol. xxiii. p. 578) I said that Prof. Peirce's symbol of inclusion, as defined by him in his "Logic of Relatives," was equivalent to the words "is not greater than." This however is not quite correct; for though Prof. Peirce speaks of this symbol as equivalent to the words "is as small as," he also speaks of it as denoting "inclusion," and his illustration $f \prec m$ may be read, *The class f is included in the class m.* In my notation the analogous composite symbol $f : m$ may be read, *The statement f implies the statement m.* If for f in my notation we read *He belongs to the class f*, and for m we read *He belongs to the class m*, then my $f : m$ will coincide in meaning with Prof. Peirce's $f \prec m$; but this does not alter the fact that my f differs in meaning from his f, that my : differs from his $\prec$, and my m from his m. Mr. Venn, in his recent paper in the *Proceedings* of the Cambridge Philosophical Society, speaks of these distinguishing features of my method as unimportant, and he regards my definitions of my elementary symbols as "arbitrary restrictions of the full generality of our symbolic language." But Mr. Venn overlooks the fact that all accurate definitions are more or less arbitrary restrictions of language, and he also seems to me, in this particular case, to mistake *vagueness* for *generality*. Philosophical investigations that begin with *Let x = anything* commonly end with *x = anything*, a result which, whatever may be thought of its generality, does not add much to our knowledge.

HUGH MCCOLL

73, Rue Siblequin, Boulogne-sur-Mer, April 26

The Formation of Cumuli

THIS afternoon the air to a great distance above the surface of the earth has been filled with fluttering dry leaves. For some weeks no rain has fallen in this vicinity, and a cold northerly wind has prevailed. To-day, for the first time during the continuance of this cold and rather clear weather, the hill-sides having a southern exposure have begun to be sufficiently warmed to cause upward currents of air along their surface. The effect has been curious: piles of cumuli have formed persistently in certain quarters of the sky, and eddying masses of leaves caught up along the hill-sides have been falling apparently from the under surface of the dense masses of cloud. My attention was first caught by the fall of chestnut and other varieties of leaves, which must have traversed a long distance, as there are no trees of the sort near at hand in the direction from which the wind was blowing at the time. Whilst walking near an elevated ridge of ground an hour later it was my fortune to catch sight of a thick mass of leaves rushing directly up its side and pouring apparently into the bosom of a dark cloud which overhung the hill. This cloud remained almost stationary, although there appeared to be a lively breeze along its under surface, the leaves darting forward very swiftly. The entire phenomenon was quite interesting as affording an illustration of the method of formation of clouds of the variety named. M. A. VEEDER

"The Oldest Ocean Post Office"

IN NATURE, vol. xxiii. p. 254, just received here, it is stated that in Magellan Straits there has been for some years past, chained to a rock there, a barrel from which passing ships take letters for the direction they are going in, leaving others for the opposite quarter; it is added that up to the present no abuse of the privileges of this primitive post-office has been reported.

In Victor Hugo's romance, published in English, some fifteen years ago, as "The Toilers of the Sea," a tale of the first quarter of this century, he makes one of his sailors tell another about such an "Ocean Post Office" at Cape Famine in Magellan Straits. Cape Famine was the scene of an early settlement which—in that bleak place—was entirely dependent on the outside world for means of subsistence, and when these, on one occasion, failed, through delay in the arrival of a ship, the colonists died; the circumstance giving the place its present name. The existing colony in Magellan Straits, about twenty miles from Cape Famine, is a Chilian settlement called Punta Arenas, or Sandy Point. Its trade is in guanaco and emu skins, brought to it by the Patagonian Indians. The colonists do a little also in agriculture, coal-mining, and gold washing.

Sailing-ships invariably now go round Cape Horn; the narrowness of the Straits at some points, their strong currents, and the alternating fogs and wild winds that prevail making the passage a very risky one for such vessels as are now employed in ocean navigation. There are however two steamship companies, a Liverpool and a Hamburg one, whose vessels pass through the Straits, and, touching at Sandy Point, insure nearly weekly communication between that place and the east and west. But the oldest commanders of these steamers know of no such institution as an ocean post office in Magellan Straits. Indeed at Sandy Point there have long been the usual facilities for postage, and the plan of the barrel is therefore not needed in the Straits.

That plan is adopted in "Post Office Bay," in one of the uninhabited Galapagos Islands, and possibly that fact, or the adoption of some similar device in the Straits at a time, long ago, when there was no settlement there, and of which a tradition may still remain, may have suggested Victor Hugo's narrative, which again may have been the origin of the paragraph quoted in your columns.

ARCH. ROXBURGH

Valparaiso, March 23

JOHN DUNCAN, THE ALFORD WEAVER-BOTANIST

THE subscriptions spontaneously sent for the purpose of forming a fund to raise this deserving old botanist above the need of accepting parochial relief have now reached the handsome sum of 322*l.* 19*s.* 10*d.* Of this sum there were sent through NATURE 73*l.* 6*s.* 9*d.*; to Mr. Jolly, Inverness, 223*l.* 10*s.* 10*d.*; to Alford direct, 90*l.* 19*s.* 7*d.*; through the *Free Press*, Aberdeen, 12*l.* 9*s.*; and through the *People's Journal*, Aberdeen, 1*l.* The names of the subscribers to the NATURE Fund have already been published here. The list of the others is much too long to be inserted, the very length showing the wide-spread interest excited by the case. It includes above 300 separate subscriptions, ranging from 30*l.* from Mrs. Alfred Morrison of London, to 1*s.* from a working man and from a child botanist, and the names of many of our most eminent scientists. Some interesting details might be given of the warm sympathy expressed in the case; the wording of special subscriptions, some large sums from nameless donors, and the plans adopted by different persons in different parts of the country interested in the old botanist, to gain the help of the generous: but want of space prevents these being entered on. One item deserves mention, namely, the interest manifested in the case by several scientific societies already mentioned in NATURE; though it must be added that the absence of the names of some societies especially devoted to Botany, and of the University of Aberdeen, which received the gift of John's herbarium, is not a little strange. The action of these generous societies is no doubt a not unimportant means of assisting scientific inquiry and "endowing research." As already stated, Her Majesty was graciously pleased to present a gift of 10*l.*

A trust-deed has now been formally executed and signed by John Duncan, disposing of the money thus subscribed, and his books and other possessions, during his life and after death, vesting all powers, with certain discretionary liberties, in seven trustees, provision being made for their permanent continuance. These trustees consist of Mr. William Jolly, H.M. Inspector of Schools, Inverness, whose sketch of Duncan in *Good Words* in 1878 first drew attention to the old man, and whose recent appeal in his behalf has resulted in the present ample provision for his comfort, Mr. Farquharson of Haughton, near Alford, chairman of the School Board of Alford, the Rev. Mr. Gillan, and the Rev. Mr. Brander, the Established and Free Church clergymen of Alford, and three other gentlemen personally interested in Duncan; the permanent trustees of his property, if any remain, to be the ministers of the Established and Free Churches of Alford and the Chairman of the School Board of Alford, with power to add to their number, so that the full number shall never be under five. It is provided, that he agrees to the provision made for him during his life, which is ample, and that whatever sum remains at his death shall be vested in safe securities and the interest arising therefrom devoted to the foundation of scholarships or prizes for the promotion of science, especially Botany, in schools in certain parishes named, in the Vale of Alford; his books, which are numerous and good, especially those on Botany, being gifted to the parish of Alford, for the same object. Meantime the greater part of the money in hand will be invested at good interest.

It must be gratifying to the subscribers to know that not only will the comfort of the old botanist be secured for the remainder of his life, but that any surplus, which is almost certain to be considerable, will promote for all time the pursuit of those studies that have made Duncan famous, among the children, male and female, of the district in which he has achieved his own scientific work. The worthy man, now in his eighty-seventh year, is frail, and the past severe winter has been hard upon him, as upon all aged people; but he may, and probably will, survive for some years to come. His gratification and gratitude at the kindness recently shown him are expressed with childlike depth and sincerity. Any remaining subscriptions offered should be sent without delay to Mr. Jolly, Inverness, in order that all requisite arrangements may be completed.

ELECTRIC LIGHTING

I.

ONE of the greatest experiments ever made in street illumination by means of the electric light was commenced on March 31 in the City of London. The enterprise of the City authorities in this direction is the more commendable, inasmuch as they had previously tried electric lighting on the Holborn Viaduct and in Billingsgate Market with very poor success. In fact, in these two instances the experiment was a decided failure.

Now however, gaining experience from the advances that have been made in other directions, and especially from the great success attending the illumination of several railway stations, the City authorities determined to divide the City into three districts for the purpose of experiment.

1. The London Bridge district: embracing London Bridge, Adelaide Place, King William Street, the front of the Royal Exchange and Mansion House, the Poultry, a part of Cheapside as far as King Street, the upper part of Queen Street, King Street, and the Guildhall Yard.

2. The Blackfriars Bridge district: embracing Blackfriars Bridge, New Bridge Street, Ludgate Circus, Ludgate Hill, St. Paul's Churchyard (north side), and the remaining portion of Cheapside beyond King Street.

3. The third district has not been lit up, and therefore we need not refer to it.

The first district is being lit up by Messrs. Siemens Brothers at a total cost of 3725*l.* for the twelve months, replacing 138 gas-lamps. The other district has been lit up by the Anglo-American Electric Light Company, on the Brush system, for a total cost of 1410*l.*, replacing 150 gas-lamps.

Before drawing any comparison between these two systems it will be just as well to describe how each has been carried out

The Messrs. Siemens have applied to their (No. 1) district six powerful lights, fixed at a height of 80 feet from the street level upon tall latticed iron masts similar to those which are used on many railways for signalling purposes. They have also twenty-eight smaller lights, carried upon special iron posts, considerably higher than the ordinary lamp-posts, being 20 feet from the pavement. The powerful lights, fixed high up in air, are used more for the illumination of open spaces, and this system—a special feature of Dr. Siemens'—has been very extensively adopted at the Albert Docks, Blackpool, and other places. The central station of the Siemens system is in Old Swan Lane. Here three engines, supplied by Messrs. Marshall of Gainsborough, of their semi-portable type, and of 10-horse power each, fitted with an admirable automatic expansion gear (Hartnell's) specially applicable to engines used for electric lighting purposes, are fixed. Two of these engines are always at work during the time of lighting, but one is kept in reserve, ready at a moment's notice to replace either that may fail. These engines, by means of beltings and a counter-shaft, apply their power to various dynamo-machines of the well-known Siemens type. Each of the high lights is worked by a separate and distinct dynamo-machine, with which it is connected by separate conducting-wires. The wires throughout the whole of the City are of thick copper, very well insulated, and laid under ground after the customary manner of laying down wires for telegraphic purposes. The smaller lights are worked by alternating currents on the system with which we are familiar on the Thames Embankment applied to the Jablochkoff candle. In Swan Lane there are two alternating current machines each working two circuits of seven lights each, the lamps being arranged so that consecutive lamps are not in the same circuit, and by that means, if any accident should occur to one set of lamps it would only extinguish one out of two lights in a street, and not throw the whole district into darkness, which would be the case if all the lights were worked on one circuit. The field-magnets in all the large dynamo-machines are excited by a similar dynamo-machine, while the magnets of the alternating current machines are fed by currents from a smaller continuous dynamo-machine. Each large machine absorbs between 4- and 5-horse power, but the alternating machines require much less. The furthest light from the generating centre —Old Swan Lane—is that in front of the Guildhall, which is nearly three quarters of a mile distant, involving a length of wire of 2500 yards (a return wire being used), whose total resistance does not exceed one Siemens' unit. The illuminating power of the high lights is estimated to be 6000 candles, but it is well known that this estimate of the illuminating power of an electric light is a very wild one. There is no doubt that the lights are very powerful, and a stream of brilliant illumination is thrown all over such an area as that in front of the Royal Exchange. The Siemens' lamps burn for eighteen consecutive hours, owing to the size and length of the carbons used. They are provided with reflectors which throw a bright cone of light down in a very peculiar way, giving to this experiment a very marked feature.

There is no doubt whatever that where it is required to illuminate a large area this is very much more efficiently and economically done by using one single powerful light high up in air, than by distributing several smaller lights over the surface. In the former case the light is more evenly, uniformly, and perfectly diffused, in fact it acquires the character of bright moonlight, while in the latter case the light is distributed in patches of intensity and darkness over the whole space.

When streets are dealt with the conditions are different, and it is here quite easy to show that economy and efficiency are provided for by properly distributing smaller lights along the street. The Messrs. Siemens have set to work to solve this problem in a scientific way, and Mr. Alexander Siemens, under whose control and management the system has been carried out, can show mathematically that to distribute light uniformly and properly a certain definite proportion should exist between the height of the posts and the distance at which they are apart. That this has been carried out is abundantly evident by the very even way in which light is distributed along Queen Street, King William Street, and Cheapside. Indeed it is difficult to see any break in the intensity of the light along the route—a proof that the practical application of the law very nearly approaches its theoretical limit. The theoretical point to be aimed at is that the height of the poles should be to half the distance between them as 1 is to the square root of 2. This has not been absolutely obtained, but a very close approach to it. The small lights only give an illuminating power, according to Messrs. Siemens, of 300 candles, and this probably is well within the mark. Comparisons between lights of low intensity are very easily and accurately measured; it is only when a power equal to thousands of candles is arrived at that the failure of comparison with a standard candle becomes evident.

The high lights have not been burning uniformly with that steadiness that success demands. Instances of failure are not numerous, though they have been frequent. The smaller lights, on the other hand, have worked more uniformly, and have given considerable satisfaction. The strong shadows thrown by the high lights have a very weird-like effect in certain positions, and the vibration of the lamp gives to the shadow of the pole that supports it an unsteadiness that has led the unwary to imagine in many instances that the pole itself was shaking. Could the shadows be removed from the effects of these high lights the effect would be very fine; as it is they detract enormously from the beauty of the lamps. The effect of the high lights to those standing below is excessively pleasing, and doubtless in warmer weather will be more highly appreciated than it has been during the past week. It is when crossing streets, and especially when crossing such a busy thoroughfare as that in front of the Mansion House that these lights show their efficiency to advantage. It is quite amusing to see how the *gamins* of London have taken advantage of the combination of electric lighting and asphalte road to convert the whole City into a gigantic skating-rink. Hundreds of boys are to be seen every night disporting themselves on their roller-skates.

(*To be continued.*)

WEATHER WARNINGS

IN a lecture on Solar Physics delivered at South Kensington on Friday last Prof. Balfour Stewart stated that he believed one great cause of weather changes to be solar variability in which we have periods of short length, as well as others extending over many years.

These weather changes, it is sufficiently well known, are propagated from west to east after they have once appeared.

Again there are variations in the diurnal declination range which may be said to constitute magnetic weather.

These are also caused by solar variability, and it is suspected that they are likewise propagated from west to east, although more quickly than the well-understood changes of meteorological weather.

It would thus appear to be at least possible that British magnetical weather of to-day may be followed by corresponding meteorological weather five or six days hence.

Prof. Stewart has made a preliminary trial, which induces him to think that this is the case, and that it

may ultimately be possible to forecast British meteorological weather by means of magnetic weather some five or six days previous to it.

BAROMETRIC GRADIENT AND WIND

I HAVE often felt surprised that the superiority in force of northerly and easterly as compared with southerly and westerly winds accompanying any given amount of barometric gradient has, at least until recently,[1] excited but little attention, seeing that the superiority in question is almost sufficient to suggest itself to any student of daily weather-charts. The comparison of anemometric records for the elucidation of this subject can only be imperfectly made, owing to the fact that there are very few situations at which an instrument can be erected which shall have a really equal exposure to winds from all points of the compass; neither is it possible, as I think, in comparing anemographic records from stations at our different coasts to eliminate the various effects of local inequalities of the earth's surface upon the force of the winds. There are two methods which can be employed in the investigation of this question, which seem to yield reliable, though necessarily somewhat rough and imperfect, results. One of these is to examine separately the anemographs of our imperfectly, but moderately well-exposed, inland stations, in relation to various values of barometric gradient in different directions. The other method is to discuss the means of estimated wind forces in relation to amount and direction of gradient for a large number of years and at a large number of stations. I have hitherto but partially and tentatively employed these two methods, but the results arrived at may possibly be of interest to some readers of NATURE. The mean wind velocities at Stonyhurst Observatory, obtained by me from the hourly readings published by the Meteorological Committee for the years 1874 to 1876 inclusive, for different moderate amounts of atmospheric gradient are as follows:—

Gradient per fifteen nautical miles.	Mean velocity in miles per hour of winds from points between S.S.E. and N.W. (inclusive).	Mean velocity in miles per hour of winds from points between N.N.W. and S.E. (inclusive).
·006	4·31	5·53
·009	5·90	6·82
·012	7·79	9·63
·015	11·09	13·97
·018	13·03	15·29

The mean wind velocities at Kew Observatory for the same period for similar gradients are as follows:—

Gradient per fifteen nautical miles.	Mean velocity in miles per hour of winds from points between S.S.E. and N.W. (inclusive).	Mean velocity in miles per hour of winds from points between N.N.W. and S.E. (inclusive).
·006	4·14	6·88
·009	6·41	8·63
·012	8·37	10·93
·015	11·21	14·27
·018	13·56	16·98

This shows that for any given (moderate) gradient winds from north and east points are stronger than those from south and west points at these stations. The second method, in which the estimated wind-forces have been employed, has been tried by me in the cases of twelve of our English stations for periods varying from ten to three years. The stations examined have been Shields, York, Nottingham, Liverpool, Hurst, Scilly, Dover, London, Oxford, Cambridge, Yarmouth, and Jersey. At all these stations, excepting Liverpool and Jersey, with very low gradients (viz. from ·001 to ·005 inch for fifteen miles), mean estimated wind forces from points between north-north-west and south-east, inclusive, have been higher than those from points between south-south-east and north-west inclusive. With the higher gradients we necessarily find results opposed to this in the cases of stations having a good exposure on the west or south and a bad exposure on the north or east, just as, on the other hand, we find the result above mentioned unduly heightened at stations which have only a good east or north exposure. If however we take stations whose exposure, though not unexceptionable, seems tolerably fair, we find that with somewhat steep as well as with low gradients, north and east winds accompanying any given amount of gradient have a higher estimation than south and west winds accompanying the same. The following table shows results at which I have arrived from an examination of the reports from three stations, viz. the two inland stations of Nottingham and London and the one sea station of St. Mary's, Scilly, which last, while very well exposed to all winds, is perhaps most perfectly so to those from the Atlantic.

	Gradient in inches per fifteen nautical miles.	Mean estimated force of equatorial winds (Beaufort scale).	Corresponding approximate velocity (miles per hour).	Mean estimated force of polar winds (Beaufort scale).	Corresponding approximate velocity (miles per hour).
Nottingham	·001 to ·005	0·43	5·2	1·06	8·3
	·005 to ·010	1·88	12·4	2·26	14·3
	·010 to ·015	2·99	17·9	4·06	23·3
	·015 to ·020	3·64	21·2	4·61	26·0
	·020 to ·025	4·41	25·0	5·35	29·9
London	·001 to ·005	0·91	7·5	1·31	9·5
	·005 to ·010	1·45	10·2	2·00	13·0
	·010 to ·015	2·24	14·2	2·93	17·6
	·015 to ·020	3·01	18·0	4·18	23·9
	·020 to ·025	3·64	21·2	4·85	27·2
Scilly	·001 to ·005	2·42	15·1	2·49	15·4
	·005 to ·010	4·24	24·2	4·86	27·3
	·010 to ·015	5·45	30·5	5·68	31·7
	·015 to ·020	6·40	36·4	6·49	36·9

The suggestion which I offer in explanation of this difference of force in the two classes of winds is made with some diffidence, since it involves a hydrodynamical question, the solution of which is somewhat difficult. Since the atmosphere is of greatest density near the poles, while barometric pressure is less near the poles than over the tropics, the pole-ward, and, under the effects of the earth's rotation, eastward movements of the atmosphere, at any given considerable altitude above the earth's surface, must necessarily greatly exceed the corresponding movements at the surface of the earth. "The planes of equal pressure receive," in short, "an ellipsoidal form, the major axis of which is perpendicular to the axis of the earth."[1] Thus the polar areas of low pressure must be far more permanent and far better marked in the upper than in the lower regions of the atmosphere; consequently gradients for westerly winds when occurring at the earth's surface must commonly extend into the higher regions of the atmosphere; while gradients for easterly winds must, on the contrary, be usually accompanied by gradients for westerly winds at no great distance above them. Observations of the movements of the upper clouds, and also of the winds experienced at the summits

[1] Sprung, "Studien über den Wind und seine Beziehungen zum Luft-Druck," ii. p. 6.

[1] Hann, "Zeitschrift der österreich. Ges. für Meteorologie," vol. xiv. p. 35.

of high mountains, fully establish this fact. Observations of the upper clouds further indicate that when a cyclonic disturbance travels eastward in our latitudes, the passage of its centre is usually accompanied (or, more strictly, followed) only by a temporary backing and subsequent veering of the westerly upper-currents, showing that where we have circular isobars at the earth's surface, we should find in the region of the cirrus merely a loop or bend in the isobars for that altitude, could such isobars be drawn. Could we in short have a weather-chart confined to the region of cirrus, we should see in it, in lieu of a deep cyclone, a shallow "secondary" travelling round a portion of the great polar area of depression.

It is true that north-easterly winds may thus be subject to more retardation due to friction at their upper surface than south-westerly winds. But in a fluid like the atmosphere the whole effect of this retardation must be conceived as almost insignificant.

The question, then, that I would ask is this:—May not the fact that any given gradient for an east wind is wholly contributed by the strata of atmosphere near the earth's surface, while a similar gradient for a west wind is contributed by the whole mass of atmosphere overhead, be imagined, consistently with what we know of the mechanics of the atmospheric currents, to give a greater force of wind in the former than in the latter case, at the surface of the earth?

There is one other point to which I may be here permitted to call attention, though it relates to language alone. I have employed above, consistently with common usage, the expression "gradient for" a particular wind; but this expression appears liable to the objection that it involves a hypothesis, and one which is moreover not in accordance with fact. "A gradient for a south-west wind" signifies a distribution of pressure in which isobars lie south-west and north-east, and in which the lowest pressure is in the north-west and the highest in the south-east. But it is only in the higher latitudes, and on a level surface such as the sea, that this distribution is actually accompanied by a south-west wind. In inland localities, even as far north as the latitudes of the British Isles, it is accompanied by a wind between south-south-west and south; in lower latitudes by a wind still more from the higher to the lower pressures, and finally at the equator such a distribution of pressure would be accompanied by a south-east wind. Further, the expression leads to the needless ignoring of the more local deflections of the winds produced by irregularities of the earth's surface. Would not the expression "north-west*ward*" gradient, simply indicating that barometric pressure decreases most in a north-westward direction, be more correct and equally intelligible? Such a gradient would be one for winds between south-west and south in our northern latitudes, for winds between north-east and east in corresponding southern latitudes, and for winds from the intermediate points over intermediate portions of the globe. "North-west*ward*," "north-*ward*," and "north-east*ward*," &c., gradients, are moreover slightly shorter expressions than gradients "for south-west," "for west," "for north-west winds," &c.

W. CLEMENT LEY

SCIENCE IN CHINA[1]

I.

THE Department for the Translation of Foreign Books at the Kiangnan Arsenal, Shanghai, which has for its object the translation and publication of books relating to the arts and sciences of the West, was established towards the close of the year 1869, mainly through the instrumentality of Messrs. Hsü and Hwa, natives of Wuseih, and who at that time were on the staff of officials at the Kiangnan Arsenal. The causes which led to the commencement of this important undertaking are, however, traceable to a much earlier date. In fact, to find a suitable starting-point for its history, it is necessary to go back to the earlier portion of the lives of these two Chinese gentlemen.

[1] By Mr. John Fryer, Chief Translator to the Chinese Arsenal.

Wuseih is an important city on the borders of the Ta Hu, or Great Lake, in the province of Kiangnan, and has long been noted for its industrial pursuits, as well as the energy and enterprise of its inhabitants, many of whom have emigrated to Japan at various times. It was in this busy place that a little *coterie* of intelligent scholars was formed, all deploring the hollow and unsatisfying nature of the ordinary routine of Chinese studies. They determined to push their investigations in a more useful and promising field by endeavouring to become acquainted with the great laws of nature, and to gather as much information as they possibly could respecting the various branches of science and art.

Without organising themselves into a society, these aspirants for intellectual light used to have occasional meetings of an informal kind for mutual improvement, each person explaining any new facts or ideas he had acquired. The works of the early Jesuit fathers on mathematics, astronomy, and kindred subjects were carefully read, as well as original native works. But at last, during a visit to Shanghai, they found a valuable prize in Dr. Hobson's translation of a treatise on Natural Philosophy, published at the London Mission Hospital in Canton in the year 1855. This book, though of a very elementary character, was like the dawn of a new era upon their minds, enabling them to leap at one bound across the two centuries that had elapsed since the Jesuit fathers commenced the task of the intellectual enlightenment of China, and bringing them face to face with the results of some of the great modern discoveries. Apparatus was extemporised at their homes to perform the various experiments described in its pages, and every new theory or law was put to the test as far as their limited means would permit. Frequent papers were written and circulated from one to another, while queries were continually started by individuals asking for more information on difficult subjects. A pile of such manuscripts accumulated in the house of Mr. Hsü, who, with his son, formed a sort of centre for this little oasis in the midst of a vast desert of ignorance and superstition. Unfortunately, however, these manuscripts were all destroyed when the Taiping rebels captured the city, and the little company were glad to escape with their lives to the neighbouring hills, among which they found a temporary refuge. Even in these trying circumstances they were able to turn their knowledge to good account in different ways so as to alleviate their own hardships as well as those of their fellow-sufferers.

In the third moon of the first year of Tung-che, or 1862, an Imperial edict called upon the Governor-General of the "Two Kiang" provinces to search throughout his jurisdiction for men of talent and ingenuity, and versed in the arts and sciences, who should assist in improving the condition of the Empire. H. E. Tséng Kwo-fan accordingly selected six men, whose names were duly forwarded to Peking. Among the number were Messrs. Hsü and Hwa, whose reputation as scientists had by this time extended far beyond their native town. They were afterwards invited to an interview with the Governor-General at Anching, and were at once retained on his staff, with the view of their being able to study and perfect themselves in the more useful branches of the foreign arts, sciences, and manufactures.

At that time the rebels were in possession of Nanking, and the surrounding country was in a most unsettled state, so that little could be done in the direction of improvement or study. Mr. Hwa, however, was engaged with others in collecting and preparing such scientific books as China then possessed. This work was after-

wards continued at Nanking, where, under the auspices of the Viceroy, an establishment was commenced for the publication of useful books. Many valuable works, such as Mr. Wylie's translation of Euclid, the Differential and Integral Calculus, Dr. Edkin's translation of Mechanics, and similar treatises, have already been republished there, and the establishment is still in existence.

While Mr. Hwa was engaged in this kind of labour, Mr. Hsü was called upon to perform a task of a very different kind. The Viceroy required him to build a steamboat, and reluctantly he consented to make the attempt. He first made a model of an engine from the somewhat rough illustrations in Dr. Hobson's work before referred to. This proving to be a success, he was encouraged to proceed with the more difficult task assigned him. By means of Chinese tools and materials, and such ideas as he contrived to get through looking carefully over a small steamer at Anching, he managed to prepare his designs, and commenced his work with no foreign assistance whatever. He met with a most determined opposition from local officials, but, assisted by his son and encouraged by the Viceroy, who took a lively interest in the proceedings, the work was at length completed; not, however, without at least one entire failure. The steamer, which was of twenty-five tons measurement, was able to make 255 *li*, or about 85 miles, in fourteen hours, and to do the return journey in less than eight hours at her trial trip on the Yang-tse in 1865. The Marquis Tsêng, now ambassador to England, also took great interest in this little craft, giving her the highly classical name of *Wang-kao* or *Yellow Swan*, and making several trips in her on the Yang-tsze.

It will be readily granted that the experience gained under so many difficulties ought to have given Mr. Hsü and his son somewhat of an insight into foreign arts and sciences, and to have raised them far above the level of the best of their fellow-countrymen. Not contented, however, with the small stock of knowledge they felt they possessed, they made several visits to Shanghai, in some of which they were joined by Mr. Hwa, with a view to making new mental acquisitions. During these visits they made the acquaintance of Mr. Li Shan-lan, the celebrated native mathematician, who was then translating with the Rev. J. Edkins and Mr. Wylie such works as Whewell's "Mechanics," Herschel's "Astronomy," Euclid, the Calculus, &c., at the London Mission. On these occasions they added largely to their intellectual attainments. They also gained many new ideas from other well-known Sinologues, such as the Revs. Messrs. Muirhead and John, and Dr. Williamson, for whom they often express much respect.

At length deciding to settle in Shanghai for the convenience of carrying on their investigations and studies in the vicinity of foreigners, they obtained from H. E. Tsêng Kwo-fan a mandate attaching them to the staff of officials at the Kiangnan Arsenal, which had recently been commenced. Here they arrived in the beginning of the year 1867, and soon endeavoured, in connection with the Arsenal directors, Fung and Shen, to organise methods by which their long-cherished hopes might be realised and their thirst after knowledge satisfied. Their aspirations finally resolved themselves into a definite form, and led them to devise a plan for the translation and publication of a series of treatises on the various branches of Western learning that should bear some resemblance to the *Encyclopædia Britannica*, of which they had ordered a copy from England. In this manner they hoped not only to instruct themselves, but to diffuse the knowledge they had acquired with so much pains among their fellow-countrymen, and leave behind them a lasting name throughout the Empire. It was also imagined by them that such a series of treatises would prove especially useful as text-books in various educational establishments of a high order, which it was then hoped would soon be instituted in the different provinces.

This scheme was warmly taken up by the directors of the Arsenal, who easily obtained the permission of the Viceroy to begin to carry it out on a small scale by way of experiment. Various foreign gentlemen were applied to for their services, but without success, till at last a commencement was made by Mr. Fryer, who at that time was editing the Chinese newspaper published at the *North China Herald* Office in Shanghai. He was asked to purchase a collection of suitable European books, and to begin at once to translate a work on Practical Geometry with Mr. Hsü, jun. Subsequently Mr. A. Wylie's services were secured for a treatise on the Steam Engine, with Mr. Hsü, sen., while Dr. Macgowan undertook the translation of a work on Geology with Mr. Hwa. These three books, which formed the beginning of this large undertaking, were translated at the residences of the Europeans above named. It soon became manifest, however, that it would be impossible to carry on the work successfully except at the Kiangnan Arsenal, where the books were to be printed and published, and which is distant about four miles from the foreign settlement. Here Mr. Fryer was pressed to give his whole time and attention to translation, and in June of 1868 commenced his labours in a building which was set apart for that purpose. The earliest publications gave such satisfaction to the Viceroy at Nanking that he ordered the operations of the translation department to be extended; the immediate result of which was the addition of Mr. (now Dr.) Kreyer to the regular staff. Subsequently when the Government school for interpreters had been removed from inside the Chinese city to the arsenal, Mr. (now Dr.) Allen's services were re-engaged to conduct it, and he was further asked to give a portion of his time to the work of translation. Dr. Kreyer, after rendering effective service as a translator for some time, left his post for that of interpreter to the Taotai of Shanghai, much to the loss of the department. The vacancy was afterwards filled by Dr. Suvoong, a Chinese graduate of the United States, who has begun to enrich the collection of books by translations of medical and other works, for which task his long residence and studies in America have well qualified him.

The number of the native members of the staff has been subject to frequent changes. At present there are five Chinese gentlemen who are engaged either in writing the translations or in preparing the various books for publication. Among this number Mr. Hsü, sen., is the only one who has remained constantly at his post from the commencement, and whose desire for knowledge does not yet appear to abate, although he is now well advanced in years. Others have worked for longer or shorter periods, and then have either grown tired of such monotonous labour, or have accepted official appointments that were offered to them. This continual changing has not been without injurious effects in some cases. Either important books have been left half finished, no one liking to take up another's work, or if finished the manuscripts have been taken away or passed from one to another, so that after the lapse of a year or two they cannot be found.

Among the officials who have left the work for higher appointments may be mentioned H. E. Li Fung-pao, the present Minister to Berlin; Mr. Hsü, jun., who has just started to join him as secretary, and who was lately Director of the Shantung Arsenal; Mr. Hwa, who has been Director of the Tientsin Powder Works, and now is Resident Curator of the Chinese Polytechnic Institution; Mr. Wang, who is a director of the Tientsin Arsenal; and Mr. Hwang, an *attaché* of the Chinese Legation in London. The names of several other gentlemen in important positions might also be added, all of whom were at one time or another on the staff, and manifestly derived

benefit from carrying on work which brought them into daily contact with Europeans. Viewed, therefore, merely in the light of an educational establishment, this department has been of much benefit to the Government by supplying so many intelligent and well-informed officials, all more or less imbued with favourable notions respecting foreigners and a desire to see foreign intercourse extended.

The history of Mr. Ka Pu-wei, who has for several years worked in connection with this department, is almost as remarkable as that of Messrs. Hsü and Hwa. From his childhood he had a strong leaning to mathematical studies; but not being in independent circumstances, he was obliged to support himself by keeping a rice-shop inside the city of Shanghai. Here he prosecuted his studies with such success that he was able to calculate eclipses and to prepare an almanac giving particulars respecting the movements of the heavenly bodies, which he ventured to publish. The Government alone having the authority to publish almanacs, and the country being at the time unsettled by the Taiping rebellion, he was charged with having designs against the Imperial throne, and cast into prison. He narrowly escaped with his life, but suffered imprisonment for above a year, till his friends could procure his release. He is now chiefly engaged in compiling and publishing a nautical almanac, calculated for the longitude of Shanghai instead of Peking or Greenwich, and in preparing various books of mathematical tables, for all of which his past studies have been an excellent means of preparation.

Equally interesting is the history of Mr. Li Shan-lan, who was for a short time connected with the Translation Department before his removal to Peking, as Professor of Mathematics in the University of that city. He is a native of the Province of Chekiang, and from his earliest years manifested a remarkable genius for the science of numbers. In the year 1845 he began to publish original treatises embracing different problems in the higher mathematics. On one occasion when at Shanghai he went to a chapel where Dr. Medhurst was preaching to a Chinese congregation, and showed him one of these works. This resulted in his being engaged in the London Mission, where Mr. Wylie took him in hand and translated with him several mathematical works of the highest order, as well as Herschel's "Outlines of Astronomy." With Dr. Edkins he translated Whewell's "Mechanics." Nothing in the way of science seemed to come amiss to him. Eventually he commenced Newton's "Principia" with Mr. Wylie, of which he only translated a small portion of the first book. The remainder of the first book he finished at the Kiangnan Arsenal with Mr. Fryer during the few months of his connection with the Translation Department. He seemed to enter into the most intricate of its problems with the greatest zest and enthusiasm, and often expressed his intense admiration for Newton's genius. His skill in solving the most difficult mathematical questions that could be given him was truly remarkable. Of course there are not many men of his calibre to be found in China; but still no doubt others will be brought to light through the impulse which foreign intercourse is bringing to bear upon the stagnant minds of this long-isolated nation. Now and then a lesser light than Li Shan-lan appears among the various visitors at the Arsenal, and it is reported that Ku Shang-chih, a native of Chiu-shan, is in advance of him; but this needs confirmation.

The establishment where the books are printed in the old-fashioned way from wooden blocks was first merely a small room, but has now grown into a separate range of buildings, and employs upwards of thirty hands as block-cutters, printers, bookbinders, &c., and is superintended by an under-official. Another under-official has charge of the books when printed, and is responsible for the money derived from their sale. About half-a-dozen copyists complete the *personnel* of the department.

The library of foreign books consists now of several hundred volumes, and forms probably the best collection of the kind in China. It is contemplated to make extensive additions shortly of recent important publications.

It may be mentioned that, as a mark of Imperial favour, various honorary degrees of rank have been conferred upon the native and foreign members of the Translation Department, in acknowledgment of the value of their services. Mr. Fryer, Dr. Kreyer, and Dr. Allen received diplomas entitling them to the third, fourth, and fifth degrees of civil rank respectively.

On various occasions some of the highest officials in the Empire have sent requests for books to be translated, bearing on subjects in which they took particular interest. Notably this has been the case with H. E. Li Hung-chang. Among the high dignitaries who have expressed their satisfaction at the results attained by this department, it may be mentioned that on one occasion, when staying at the Arsenal, H. E. Ting Jih-chang expressed himself in strong language as to the importance which he attached to the translation of books, compared with the work carried on in other departments. The Marquis Tsêng, who resided for a few days at the Arsenal in 1877, and has from the first been in favour of the undertaking, gave Mr. Fryer a Chinese fan, on which he had written by way of compliment a verse of Chinese poetry of his own composition, and which may be freely translated as follows:—

"Nine years have elapsed since our last conversation;
But your translations have been forwarded to me from time to time.
May your fame surpass that of Verbiest and Schaal,
As the electric light exceeds the spark of the glowworm."

(*To be continued.*)

THE GREAT VIENNA TELESCOPE

THE political and social disturbances in Ireland have of late somewhat diverted attention from the literary and scientific work done in that country. Such work has nevertheless proceeded on its quiet way despite land agitation, failure of crops, or even commercial distress; and Ireland is to be congratulated on the completion of the fine 27-inch refracting telescope, designed and constructed by Mr. Howard Grubb of Dublin for the Imperial and Royal Observatory of Vienna.

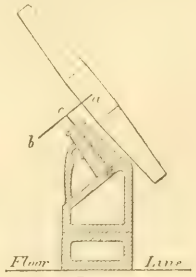

FIG. 1.

This telescope is the largest equatorial refractor at present in existence. In the year 1873 Director Littrow, of the National Observatory of Vienna, induced the then Austrian Minister of Public Construction (R. von Stromayer) to consent to the removal of the Observatory from the old site in the Vienna University grounds to a more favourable site, consisting of a level piece of ground

of some fifteen acres in extent, about 200 feet over the general level of the city, and nearly three miles to the north of the cathedral of St. Stephen's. On this plateau a magnificent edifice has been erected, which measures from north to south 330 feet, and from east to west 240 feet. The general plan of the observatory is that of a

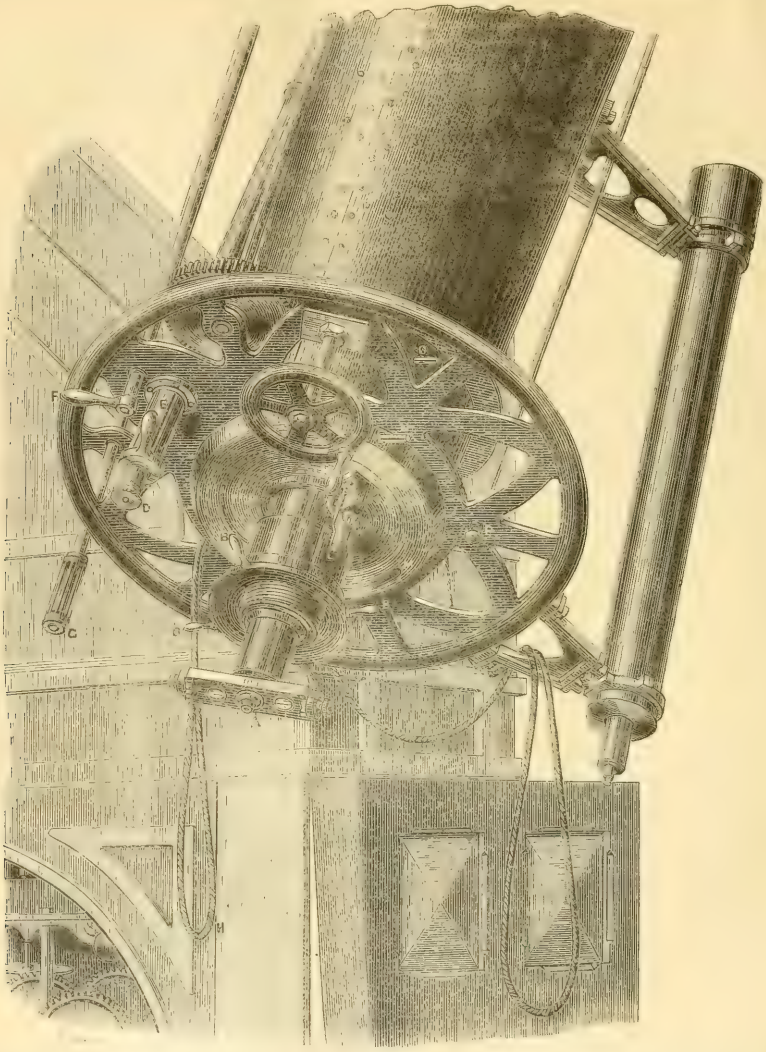

FIG. 2.—Eye-End and Breech-Piece of Telescope. A is the micrometer eye-piece; B B, handles for working the focussing screw; C, eye-piece of finder or telescope, 4 in. aperture; D, eye-piece of reader for reading right ascension and declination circles; E, handle for revolving same to point to various verniers; F, clamping handle in declination; G, slow motion handle in declination; H, clamping cords for right ascension; I, slow motion cord for right ascension; K, quick motion handle for right ascension and declination movements; L, flute key for position circle clamping; M, window through which glass position circle is viewed while illuminated from behind by beam of light from gas-lamp at end of declination axis; N, screw for slow motion in position angle; O, key for throwing into position a set of illuminators for "dark field" illumination of micrometer; P, handle for throwing into position an arm carrying one central mirror for "bright field" illumination of micrometer.

Latin cross. One great dome forms the centre, three smaller domes terminate the extremities of three of the short arms, while the fourth arm, looking south, contains the library and lecture-rooms, &c. The south *façade* is very imposing, and in it are the rooms for the director of the Observatory. In one of the smaller domes (each 27

feet in diameter) is placed a 12-inch refractor by Alvan Clark, and it is intended to have in the other two an equatorial for photographic work, and an altazimuth or comet-seeker. It seems a pity that the use of so magnificent a building should in some measure be sacrificed to architectural display, for the splendid south *façade* being devoted to domestic purposes, an enormous proportion of the observations will of necessity be made over the chimneys of the dwelling-house. The great central tower is 45 feet in diameter, and its dome and the revolving machinery to work it have been supplied by Mr. Howard Grubb, who has also put up all the domes of the smaller towers. The great dome is of a very peculiar construction. It is formed of two thin shells of steel plate varying in thickness; these are riveted on the inside and outside of a very light set of steel plate girders 18 inches deep at base and 9 inches at crown, the whole forming a cellular construction like the top and bottom of the Britannia Tubular Bridge. This form gives enormous stiffness for the amount of material used, besides possessing several points of peculiar usefulness for astronomical work, such, the more specially, as keeping the temperature of the dome wonderfully constant, even under most trying circumstances. The total weight of this steel dome, with its ribs and girders, the cast-iron sole plate, and fitting, is about 15 tons, and as the result of a series of very ingenious mechanical contrivances thought out by Mr. Grubb, the tractive force necessary to pull round this huge drum, even when resting, as at Dublin, on a temporary support and insufficiently levelled, was only 70 lbs. All these domes were constructed, so far as the framework went, in Dublin, and they have been placed for some time past *in situ* at Vienna, under the superintendence of Mr. W. K. Davis, Mr. Grubb's engineer.

The new Observatory having been well advanced in 1874 Director Littrow sent his first assistant (now the General Director), Dr. Ed. Weiss, on a tour of inspection to all the great observatories and astronomical workshops of Europe and America, with the result that Dr. Weiss recommended to his Government that an instrument of at least 26-inch aperture should be ordered from the establishment of Mr. Howard Grubb, and in the year 1875 the contract between the Austrian Government and Mr. Grubb was signed for a 27-inch refractor. The mechanical parts were nearly finished in the year 1878, but the greatest difficulties were experienced by the Messrs. Feil of Paris in obtaining perfect disks of glass for the objective, and it was not until after several trials and towards the close of 1879 that this firm succeeded in sending to Dublin disks that ultimately proved perfect. These had to be worked into the objective at Mr. Grubb's establishment, and on several occasions serious flaws were only discovered at a time when but for them the object-glass would have been complete.

The general form of the equatorial may be described as a modification of the German form. In designing it Mr. Grubb kept in view the fact that while circumpolar motion was very desirable—indeed almost necessary—for objects from the horizon to, or approaching to, the zenith, it was by no means so essential for objects beyond that to the pole. This will be evident on consideration, for nineteen-twentieths of the objects usually under observation in these latitudes are between the zenith and south horizon, and if one be observed north of the zenith its apparent rate of progression is so slow that a very little motion of the telescope takes place for any given duration of observation. Keeping this in view, Mr. Grubb has adopted the form shown (Fig. 1), in which the intersection of the axes *c* is placed, not over the centre of the pier, but over the north end nearly, and this allows the telescope circumpolar motion for all objects up to the zenith. It should also be observed that this circumpolar motion gives another advantage besides that of non-reversal, viz. that it allows choice of two positions of the telescope in observing almost any object. In observing near the meridian the telescope may be used *either* to the east or west of the pier, and in observing towards the east or west the telescope can be used either over the polar axis or under. This is sometimes found to be a great convenience. The above considerations were those which influenced Mr. Grubb in deciding on the particular form for the Vienna instrument, and the result is that almost all the advantages of circumpolar motion are obtained without any serious counterbalancing disadvantages.

To enter into full details of all the various parts of this magnificent telescope would far exceed the space at our command. Up to this it has been thought impossible to apply to large equatorials those many important contrivances to save time and labour which all first-rate

Fig. 3.

instrument-makers would adapt to small instruments, but in this one all such contrivances and many novel adaptations of such have been utilised. To enable our readers to form some idea of the resources within the ready reach of the observer, we, through the kindness of the proprietors of our contemporary, *Engineering*, give an illustration (Fig. 2) of the eye-end of the tube.

In the largest telescope until now in existence, the great 26-inch refractor at Washington, the oft-recurring operation of reading the circle involved the sending of an assistant with a hand-lamp to climb up some twenty feet of the instrument, and the vernier not being in a fixed place, but moving about with the telescope, the labour and difficulty of this operation are great. In the Vienna instrument Mr. Grubb has so contrived it that the observer sitting in his chair can read the right ascension and declination circles through one single reader, all being illuminated by one gas-lamp hung on the end of the declination axis.

Another wonderful convenience is enabling an assistant

to easily turn and set the instrument to right ascension. This can be understood from Fig. 3, which is from a photograph. In the case of an instrument of the size of the Vienna equatorial, the observer requires an elaborate stage or platform of variable height and position in order to reach the eye-end, and if he has to move to another object he must descend from his chair or platform and move *it* before he can move the instrument, and then he has not the facility of sighting objects, but must adopt a sort of tentative process, climbing up and down his stage and moving it and the telescope alternately. To avoid this labour and save time an arrangement is supplied by which the assistant from the ground floor can set the instrument in right ascension, and once set in one direction, the other (declination setting) can be readily managed by the observer. The assistant is supposed to stand at the south end of the pier. He has there before him a desk on which his catalogue and paper can rest, a sidereal clock-face let into the south end of the pier, a reader telescope by which he can read the lower right ascension circle, and a hand-wheel, which by means of shafts and gearing communicate motion to the instrument in right ascension, and finally a handle which is keyed on to a screw forming the toe-bearing of the quick motion driving-shaft. By giving this handle one turn, the driving-shaft is allowed to drop down out of gear with the rest of the wheelwork, so that the clock when driving the instrument may not have the additional work to do of driving this shaft, which is necessarily a quick one as compared to the motion of polar axis itself. A lamp is attached to pier at west side, which serves to throw light on sidereal clock-face, catalogue, &c., on desk, and also to send a beam of light up through a long tube directed to the vernier of the right ascension circle which is visible through the reader. The assistant has therefore full power of setting the instrument roughly, or if desired with any degree of accuracy, in right ascension, or reading off the right ascension of an object which requires to be identified.

The tube of the telescope is made of steel plate about one-eighth of an inch thick in the centre, and tapering to about one-twelfth of an inch at the ends, the points being all lapped and riveted; it is 33½ feet in length, and lessens from 36½ inches in diameter in the centre to 27 inches at the one and 12 inches at the other end. The weight of the moving parts is between six and seven tons, and still the whole is under easy control of the muscular power of one arm.

The Commissioners appointed by the Austro-Hungarian Government to report on this telescope consisted of Prof. Ball, Astronomer-Royal for Ireland, Earl of Crawfurd and Balcarres, Mr. Huggins, Prof. J. Emerson Reynolds, Earl of Rosse, Prof. Stokes, Dr. G. J. Stoney, and Mr. Walsh, the Austro-Hungarian Consul at Dublin. On March 16 this Commission forwarded to the Austro-Hungarian Embassy in London their full approval of the performance of the instrument, thus marking the successful completion of the largest refracting telescope in existence.

It will be remembered that Mr. Grubb has built among other fine instruments the great Melbourne Reflector, the largest equatorially-mounted telescope known. He has not rested on his laurels, but is now to be cordially congratulated on a still greater accomplishment.

WHEWELL ON COLOURING GEOLOGICAL MAPS

ONE of the subjects to be brought forward for discussion at the International Geological Congress to be held this year at Bologna is the *unification des figurés*; that is to say, an attempt will be made to come to some agreement as to the signs and colours to be used on geological maps. Two things have to be indicated: *succession, i.e.* the stratigraphical position of the rock; and *formation*, by which, adopting a terminology now in much favour on the Continent, we mean the lithological character and origin of the rock, and not, as is generally understood by the word in this country, a subdivision of the stratigraphical series. I have found among Prof. Sedgwick's papers a scheme drawn up by Dr. Whewell nearly half a century ago, which I have thought might be of use to those who are considering this question, and of interest to many besides. It is dated from Dublin, 1835, where he was attending the meeting of the British Association, and it was probably suggested by the publication of Griffiths' map.

William Smith shaded up to the lowest beds of the various groups into which he divided the strata, in order by contrast to mark more strongly the coming in of a new series, but he does not seem to have adopted any system beyond sometimes taking such tints as were suggested by the predominant colours of the rocks represented. Salter, I remember, proposed a scale of colours founded on the spectrum, but the scheme proposed by the late Master of Trinity I do not remember to have seen put forward before.

THOS. MCK. HUGHES

Trin. Coll., Cambridge, April 26

Proposal for a Systematic Scale of Geological Colours

THE objects which it would be desirable to secure in fixing the scale of colours for a geological map appear to be the following:—

1. That the different members of the geological series should be coloured in a manner somehow depending on their *place in that series*, so that successive rocks are distinguished.

2. That *this* distinction (of succession) should be governed by some *general principle*, and should not be merely arbitrary; so that without referring to the index list the colour itself should show the difference of older and younger in the rock.

3. That the colours should also show the great leading differences of the material of the strata (limestone, sandstone, clay), so that without referring to the scale these differences should be known from the colour.

4. That *igneous* rocks should by some general circumstance in the colour be distinguished from sedimentary.

5. That the colours which are brought near each other by proximity of succession should be strongly *contrasted*.

The following method would, I think, secure these objects. It proceeds on the supposition that there are three primary colours—Red, Yellow, Blue—and that any two of these mixed in considerably different proportions make several shades of intermediate colour; thus between red and yellow we have many shades of orange, proceeding from pure red, through reddish orange, to orange, yellowish orange, and pure yellow; in like manner we have many shades of green between yellow and blue, and many shades of purple between red and blue. Our scale can be subdivided as far as these shades are distinguishable. We have also black, which can be combined in various proportions with each of the simple colours; thus black with successive doses of red makes brown more and more red.

The general principles which I propose are these:—

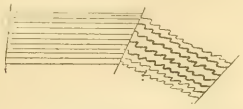
1. Let one of the above four simple colours represent the material and another the order of succession, and let successive mixtures represent successive strata of the same material. Thus let the oldest *limestone* be pure *blue*, let doses of yellow be added to mark newer and newer limestones, the chalk being a very yellow green; thus all the oolite series will be green of different shades.

2. Let the simple colour which represents succession be different for different materials, thus let *blue* represent succession for the *clays*, and let all the clays be *purple*, the oldest therefore being the reddest, and the newest the bluest purple.

In the same way let black represent *sand* strata, and let *red* represent *succession* in such strata; then the sandstones will be represented by *browns*, the oldest being the blackest, and the newest the reddest brown.

3. Let igneous rocks be represented by a general colour, as *red*, and let any order which obtains among them (succession, for example, if succession can be traced) be marked by doses of another colour, as yellow; then the igneous rocks will be all red or orange, the newest being the yellowest.

4. Let other differences (as mineralogical differences) be represented by other means, as by *hatching*. Thus granite and quartz rock, if contemporaneous, may be marked by red with the addition of lines—



According to these principles the English strata would be represented by the following colours, which may thus be denoted by letters; let Red, Yellow, Blue, *Black*, be marked by R, Y, B, *A*, and let mixtures be represented by combinations of the letters. Then we have—

Orange, R R R Y, R R Y, R Y, R Y Y, R Y Y Y.
Green, Y Y Y B, Y Y B, Y B, Y B B, Y B B B.
Purple, B B B R, B B R, B R, B R R, B R R R.
Brown, A R R R, A R R, A R, R A A, R A A A.
Unstratified rocks (primary), R.
„ „ (trap), R R Y, R Y, R Y Y, &c.
Clay slate, B R.
Oldest limestone, B, B B B Y, B B Y.
Oldest sandstone, A, A A A R, A A R.
Secondary limestone (Mountain), B Y.
New red sandstone „ A R.
Oolites „ B Y Y, B Y Y Y.
Green sand „ A R R.
Chalk „ B Y Y Y Y.

Observations:—1. The method here proposed would answer the objects above stated, for the material and order of succession are marked by their proper colours; and the sands, clays, and limestones which occur near each other would be very distinct. Thus the green sand is reddish brown (A R R) and the chalk is yellow green (B Y Y Y).

2. Perhaps it may appear an inconvenience that contiguous members of a formation of the same material are proximate shades of the same colour: thus the oolite beds would be successive shades of green (B Y Y, B Y Y Y), and might be difficult to distinguish. I answer, that the beds themselves are often difficult to distinguish, so that our language is most indistinct when our knowledge is most indistinct; again, that the inconvenience, when it is one, may be remedied by marking or hatching those strata; again, that no systematic method can be devised which will not be open to this objection.

3. The above principles being adopted, the whole range of the colours, as modified by the *succession-colour*, might be different according to the different object of the geologist. Thus if he had to exhibit the whole geology of England, *all* limestones whatever must come in between B and Y (Blue and Yellow). But if he take the secondary period only, he may use all the possible shades of green for members of that part of the series alone, and may thus make his terms more numerous.

4. If the *whole* range of the *succession-colour* be employed and exhausted on a *part* only of the geological series of strata, the strata which occur beyond this part will, in the scale used on such occasions, be without representative colours. This is an inevitable evil. We cannot combine the extremes of detail and generality. If we use all our means in expressing a part, we must for the time omit to express the remainder. We must do this when our purpose requires and justifies it.

5. When we use all our colours for part of the geological series, we still preserve the principles above proposed and the advantages which they secure, namely, that the material and the succession are both exhibited in an intelligible way without reference to the index.

6. If we thus make a part of the geological succession to occupy the whole power of our successive colour, we have different colours from those which we have when we represent the whole succession. The partial map has a different index from the general one. This is a serious evil, and must not be incurred without strong necessity.

7. It may be mentioned as an advantage of the proposed notation that many of the colours which are used in it agree very nearly with colours commonly used: as red for granite, blue for older limestones, yellow, or yellow-green for chalk, brown for some sandstones, purple for clays. The main novelties are that the oolites are green, and the coal-fields not black; but as to the latter point, query, whether a *coal* stratum be a proper geological distinction? If the coal-measures be sand or clay beds, they should be brown or purple, according to the material which is taken as characteristic.

In a given case we may have to determine the question above suggested, whether we should employ the whole range of our succession colours on a limited geological period, as, for example, the transition-period. In order to decide this consider what you want. How many limestones have you? How many sandstones, how many clay-rocks, which are to be distinguished? If the oldest limestone be pure blue, and mountain limestone pure green (B Y), we can easily interpose three or four limestones, as (B B B B Y, B B B Y, B B Y); is this a sufficient number of terms for you? and so of the rest.

Summary.—Let there be in all cases a *material colour* and a *succession colour*, namely—

	Material.	Succession.	
Limestone	B	Y	(Green)
Sandstone (black) ...	A	R	(Brown)
Clay	R	B	(Purple)
Igneous Rocks	R	Y	(Orange)

The latter two lines lead to no confusion, for though R in the clays indicates the material, it is never to be used without B, and R in igneous rocks is never used with B.

It may be observed that in the preceding scheme I have not exhausted the power of colour, for I have not used either the combinations of *black with blue* or of *black with yellow*, or the combination of *three* simple colours.

W. W.

Dublin, August 17, 1835

NOTES

We are glad to learn that the Italian Government has decided on having a deep-sea expedition in the course of this summer to explore the Mediterranean. The necessary arrangements are now being made by Prof. Giglioli, the eminent zoologist, at Florence, who will take charge of the biological part of the work. Capt. Magnaghi will be intrusted with the physical part of the work, as well as with the command of the vessel. The scientific results may be expected to be of especial interest, because nothing has been done to explore the depths of the Mediterranean beyond the short cruise in H.M.S. *Porcupine* in 1870.

Prof. Tyndall has written to the *Times* of yesterday a letter of great interest on the attitude of the late Mr. Carlyle towards modern science, which it has been taken for granted was purely hostile. But according to Prof. Tyndall, not only was Mr. Carlyle deeply interested in some of the latest researches of science, but he took great and successful pains to understand

them, and was even open to accept some of the latest developments of scientific thought. At first, for example, his attitude to Darwinism was decidedly hostile, but later on, Prof. Tyndall states, "he approved cordially of certain writings in which Mr. Darwin's views were vigorously advocated, while a personal interview with the great naturalist caused him to say afterwards that Charles Darwin was the most charming of men."

We learn from the *American Naturalist* that a proposal will be made at the next meeting of the American Association to invite the British Association to hold its meeting in 1883 in America in conjunction with its American sister. The proposal deserves consideration.

According to the *Frankfürter Zeitung*, at Nakkoo, in the Island of Lapland, an eagle was shot on the 15th ult., which measured 6½ feet between the tips of the wings. Round its neck it had a brass chain to which a little tin box was fastened. The box contained a slip of paper on which was written in Danish, "Caught and set free again in 1792 by N. and C. Andersen.—Boetod in Falster, Denmark."

We regret to learn that the printing of the "International Bulletin" issued by the U.S. Signal Office will hereafter be twelve months after date, instead of six months as at present. This seems to us a step backwards from the energetic and liberal policy of the late General Myer.

Prof. Gegenbaur, the well-known Heidelberg comparative anatomist, is said to be dangerously ill with blood-poisoning, contracted while dissecting.

The Davis Lectures for 1881 will be given in the lecture-room in the Zoological Society's Gardens in the Regent's Park, on Thursdays at 5 p.m., commencing June 16. The following are the subjects and lectures:—June 16, Whales, Prof. Flower, F.R.S.; June 23, Dolphins, Prof. Flower, F.R.S.; June 30, Extinct British Quadrupeds, Mr. J. E. Harting; July 7, The Limbs of Birds, Prof. W. K. Parker, F.R.S.; July 14, Birds Ancient and Modern, Mr. W. A. Forbes; July 21, Zoological Gardens, Dr. P. L. Sclater, F.R.S.; July 28, Chameleons, Prof. Mivart, F.R.S. These lectures will be free to Fellows of the Society and their friends, and to other visitors to the Gardens.

At the fifty-second anniversary of the Zoological Society the report of the Council on the proceedings of the Society during the past year was read by Mr. Sclater, F.R.S., the Secretary. It stated that the number of Fellows on December 31, 1880, was 3309 against 3364 at the same date of the previous year, 153 new Fellows having been elected, and 208 removed by death or other causes during the year. The total receipts for 1880 had amounted to 27,388*l.* against 26,463 for 1879. The ordinary expenditure for 1880 had been 24,753*l.*, and the extraordinary expenditure 1825*l.*, besides which the sum of 1000*l.* had been devoted to the repayment of part of the mortgage-debt due on the Society's freehold premises, which had thus been reduced to 7000*l.* This had left a balance of 879*l.* to be carried forward for the benefit of the present year. The total assets of the Society on December 31 last were estimated at 27,852*l.*, and the liabilities at 9078*l.* Amongst the works carried out in the Society's Gardens in 1880 were specially noticed the completion of the insectorium (which had just been opened to the public, and contained a collection of living insects), and the thorough repair and reconstruction of the parrot-house. The number of visitors to the Society's Gardens in 1880 had been 675,979, gainst 643,000 in 1879. The zoological lectures having been well attended during the past year, would be continued during the present season. The number of animals in the Society's collection on December 31 last was 2372, of which 703 were mammals, 1438 birds, and 231 reptiles. Special attention was called to the increasing number of presents to the menagerie received by the Society of late years, the number thus acquired having now so increased as to usually exceed the number of those obtained by purchase. Col. J. A. Grant, C.B., F.R.S., Dr. Günther, F.R.S., Prof. Newton, F.R.S., Osbert Salvin, F.R.S., and the Right Hon. George Sclater Booth, M.P., were elected new Members of Council. Prof. W. H. Flower, LL.D., F.R.S., was re-elected President, Mr. Robert Drummond, Treasurer, and Mr. Philip Lutley Sclater, M.A., Ph.D., F.R.S., Secretary to the Society.

A newly issued part of the Annals of the "Museo Civico" of Genoa is devoted to a memoir by Dr. Peters and Marquis G. Doria on the Mammals of New Guinea and the adjoining Papuan Islands, procured during the recent researches of Beccari, D'Albertis and Bruijn. In the collection amassed by these ardent explorers fifty-seven species are represented, amongst which are twenty-two Marsupials, nineteen Bats, and thirteen Rodents; *Sus papuensis*—an introduced species—was the only Ungulate met with. It will be seen, therefore, that, as in Australia, the Mammal-fauna of the Papuan sub-region may be said to consist nearly entirely of Marsupials, Bats, and Rodents. Its affinity to Australia is further shown by the presence of a Monotreme (*Tachyglossus bruijnii*), and by the occurrence of such genera as *Macropus*, *Dasyurus*, and *Dromicia*. The memoir is illustrated by eighteen excellent plates.

Mr. Thiselton Dyer writes to the *Daily News* in reference to a suggestion "that the labels of ferns, flowering and other plants in Kew Gardens should bear not only scientific but popular names." Mr. Dyer states that as far as such popular names can be ascertained they are carefully indicated on the Kew labels. "There is some misapprehension," Mr. Dyer states, "about the popular names of plants. Your correspondent seems to have proceeded on the assumption that there is a popular botanical nomenclature co-extensive with the scientific. This is very far indeed from being true even of a vegetation so thoroughly investigated as that of the British Islands. Of the plants of foreign (especially tropical) countries it is obviously, with the exception of some useful or medicinal plants, not true at all. But, as you will observe from the accompanying copy of the popular guide to the Royal Gardens, where anything like a genuine popular name exists, great prominence is given to it at Kew. . . . The popular tongue is by no means ready in finding acceptable names for the foreign plants of our gardens, and is quite content to accept from botanists Dahlia, Petunia, Phlox, Pelargonium, Gladiolus, Calceolaria, and the like."

We take the following from the May number of the *American Naturalist*:—The Kansas Academy of Science, at their November meeting, appointed a Commission to memorialise the Legislature in reference to a State Survey. Two preliminary surveys under Professors Mudge and Swallow have already been made. A more extended and thorough scientific survey is now needed. The most active geologist now in the field in this State is Prof. O. W. John, who for two years past has studied the stratigraphical geology of Eastern Kansas. Last summer Prof. F. H. Snow, with several assistants, spent over a month in Santa Fé Cañon, New Mexico, as well as in Colorado, and made important entomological collections; among them were twelve new species of coleoptera and an interesting collection of geometrid moths, comprising a number new to the Colorado plateau region. Prof. A. Hyatt, the curator of the Boston (U.S.) Society of Natural History, announces that a sea-side laboratory will be opened this year under his direction at Annisquam, Mass., three miles from Gloucester, from June 5 to September 15.

We have received copies of handy and cheap guides to the New Natural History Museum; penny guides are furnished for

each of the departments, and a guide to the whole place costs only threepence. This is as it should be.

FROM Gustav Wolf, the Leipzig publisher, we have received a copy of a most useful "Naturwissenschaftlich-mathematisches Vademecum." The catalogue is really an index, both of subjects and authors, to all recent publications of importance in physical and natural science, and is likely to prove of real service to all scientific workers.

AT the meeting on April 26 of the Institution of Civil Engineers, Mr. Walter R. Browne, M.A., M.Inst. C.E., read a paper on "The Relative Value of Tidal and Upland Waters in maintaining Rivers, Estuaries, and Harbours." The author, while declining to lay down any universal rule, held as a general principle that the main scouring agent was not the tidal but the low-water flow. This principle was supported by the following line of argument:—1. The silt, which tended to choke up tidal channels, was almost wholly due to the tidal water, and not to the fresh water. 2. The tidal water brought up more silt on the flow than it took down on the ebb; *i.e.*, on the whole it tended to choke the channel, not to scour it. 3. The low-water flow, if left to itself, scoured away the deposit and kept the channel open 4. Hence it was concluded that where the two acted together, the scour must be due mainly, if not entirely, to the low-water flow, and not to the tidal flow. It was added that low-water scour was in its nature self-regulating, whilst tidal scour, if it once began, would tend to increase indefinitely. But the essential point was to discover the ratio of the bottom to the surface velocity under all possible circumstances, since it was obvious that the former alone had any scouring effect. Tables were given showing that the ratio of bottom to surface velocity diminished rapidly with an increase of depth; but their application to tidal channels was doubtful, because then the river, instead of being (in a theoretical point of view) indefinitely long, fell at a short distance into an estuary whose waters might be considered at rest. The author had conducted two series of experiments on the surface and bottom velocities of the River Avon, in the course of an ebb-tide. Both series of experiments showed that during the greater part of the ebb the bottom velocity was actually *nil*. When about two thirds of the ebb was over, the bottom layers of water appeared to start into activity, and to assume a velocity about two-thirds of that at the surface. This is shown by the following extract from the tables:—

Position of meter.	Time after ebb began. h. m.	Depth of water. ft. in.	Velocity. feet per sec.
Surface	1 0 ...	22 8 ...	3·57
Bottom	1 10 ...	21 0 ...	0·00
Surface	1 53 ...	14 10 ...	4·60
Bottom	2 4 ...	13 6 ...	0·00
Surface	3 45 ...	5 8 ...	3·07
Bottom	3 54 ...	5 7 ...	1·91

The following conclusions were drawn from these and other experiments:—In the largest rivers the bottom velocity is for practical purposes the same as the surface velocity. In ordinary rivers the bottom velocity bears to the surface velocity a ratio which is about three-fourths at 5 feet depth, one-half at 15 feet, and one-third at 25 feet. In tidal channels, such as the Avon, during two-thirds of the ebb the slope of the surface is exceedingly small; and while the surface velocity is large the bottom velocity is *nil*. During this period no scour, but rather deposit, is going on. For the remainder of the ebb the conditions approximate to those of an ordinary river; scour does go on, but its amount is insufficient to sweep away the silt which has been deposited, not only at the top of the tide, but also during two-thirds of the ebb. Embankments had frequently proved beneficial rather than the reverse; a fact explained by the author's experiments, since the level of the ebb tide would in consequence fall more rapidly, and the point at which the water at the bottom began to move would be reached at an earlier period. Again, the process called "dockising," or damming a river at its mouth, had frequently been condemned on account of supposed injury to the river itself, or even to the estuary in which it flowed, but, as would appear from this paper, without foundation. The results would exercise an important influence on other cases, both of theory and practice.

A SHOCK of earthquake is reported on the night of April 28 from Sicily and the province of Reggio di Calabria, and as far as Catanzaro and Monteleone.

WE learn that M. Alphaud, the Director of Public Works in Paris, has in his hands the tender of Siemens and Co. for constructing an electrical railway from the Place de la Concorde to the interior of the Electrical Exhibition. M. Alphaud has given his adhesion to the request, which will be sent with his recommendation to the Commission of Sewers appointed by the Municipal Council, that when the Exhibition shall be closed, the railway will be kept running in the Champs Elysées.

MR. PREECE has been spending a few days in Paris in order to report on the electric establishments and experiments which are being made in that city. He inspected the electric conductors of several large monuments, visited the telephonic exchanges, the Méritens factory, where are being built the magneto-electric engines ordered by the French Lighthouses Administration and the Trinity House, &c., &c.

THOSE interested in sanitary matters should see the Preliminary Report to the U.S. National Board of Health on the Relation of Soils to Health, in the supplement to the *Bulletin* of the Board for April 16. The special point reported on is the Filtering Capacity of Soils, by Messrs. R. Pumpelly and G. A. Smith.

A MEETING of the Yorkshire Geological and Polytechnic Society was held on April 27 at the Royal Institution, Hull, under the presidency of Mr. A. K. Rollit, LL.D., F.R.A.S., &c., ex-president of the Hull Literary and Philosophical Society. There was a fair attendance, including representatives from several parts of Yorkshire. A brief introductory address on recent advances in physical science was made by Dr. Rollit, after which Mr. G. W. Lamplugh, F.G.S., read a paper on "The Peculiar Intermingling of Gravel and Boulder Clay in some Sections near Bridlington." Mr. J. W. Davis, F.G.S., hon. sec., then read and remarked upon papers by Mr. A. G. Cameron of H.M. Geological Survey, on "The Subsidences above the Permian Limestone between Hartlepool and Ripon," and Mr. J. E. Clark, B.A., on "A Deep Glacial Section at the Friends' Retreat at York." Dr. James Geikie, F.R.S., was present at the meeting, and made some observations on the subject of geology generally. In the afternoon the Society made a geological excursion to the east coast at Withernsea and to the gravel-pits at Kelsey Hill near Burstwick, at the former of which places Dr. Geikie delivered a geological address.

ABOUT twenty minutes to eleven on Monday night, owing to some accident at present unexplained, the electric lights on the Brush system, one of the three with which experiments are at present being made in the City, were suddenly extinguished, leaving a large portion of the City in total darkness. The area over which the Brush light has been placed extends from Blackfriars Bridge, up Ludgate Hill, to St. Paul's Churchyard, and down Cheapside as far as Queen Street and King Street. Fortunately the old gas-lamps remain in their places while the electric light experiments are being made, and orders were quickly given for these to be lighted. Every attempt was made by those in charge of the Brush light to restore the connection, and for a

few minutes it seemed as though they had succeeded; but this only lasted for a very short time, and it was soon seen that something had gone hopelessly wrong.

THE following excursions have been arranged for by the Geologists' Association:—To Croydon, Shirley and the Addington Hills, May 7; to Grays, Essex, May 14; Sheppey, May 23.

MR. LANT CARPENTER asks us to state that in his article on Niagara in NATURE, vol. xxiii. p. 511, he attributed the article on the "Music of Niagara," in *Scribner's Magazine* for February, 1881, to Mr. Eugene Schuyler, whereas the author was Mr. Eugene Thayer, of Tremont Street, Boston, Mass.

THE additions to the Zoological Society's Gardens during the past week include a Silver Fox (*Canis fulvus*, var. *argentata*) from North America, presented by Mr. Robert Hunt L. B. Lydston Newman; a Vulpine Phalanger (*Phalangista vulpina*) from Australia, presented by Mrs. J. S. Henderson; a Goldfinch (*Carduelis elegans*), British, a Snow Bunting (*Plectrophanes nivalis*), European, presented by Mr. John Fletcher; an Eyed Lizard (*Lacerta ocellata*), South European, presented by Mr. James Wellford; an Indian Cobra (*Naia tripudians*) from India, presented by Mr. A. H. Jamrach; a Ludio Monkey (*Cercopithecus ludio*) from West Africa, on approval; two Humboldt's Lagothrix (*Lagothrix humboldti*), two Matamata Terrapins (*Chelys matamata*) from Upper Amazons, a Green-billed Toucan (*Ramphastos dicolorus*) from Guiana, three Saddle-billed Storks (*Xenorhynchus senegalensis*) from West Africa, three Roseate Spoonbills (*Platalea ajaja*) from South America, a Japanese Teal (*Querquedula formosa*) from North-East Asia, three Magellanic Geese (*Bernicla magellanica*) from the Falkland Islands, purchased; a Reeves' Muntjac (*Cervulus reevesi* ♂) born in the Gardens.

OUR ASTRONOMICAL COLUMN

THE INTRA-MERCURIAL PLANET QUESTION.—It may be remembered that when the late Prof. Watson claimed to have seen an unknown object near the star θ Cancri during the totality of the eclipse of July 29, 1878, it was objected with respect to his supposition as to its being an intra-Mercurial planet, that he had not anywhere mentioned his having seen the object at the same time as the star, or as well as the star, consequently that his circle-reading may have really applied to the latter. From Prof. Watson's official report on his observations, just published with many others, by the Superintendent of the Naval Observatory at Washington, it appears that this objection is no longer valid. Prof. Watson writes: "Between the sun and θ Cancri, and a little to the south, I saw a ruddy star whose magnitude I estimated to be 4½. It was fully a magnitude brighter than θ Cancri, which I saw at the same time, and it did not exhibit any elongation, such as might be expected if it were a comet in that position. The magnifying power was 45 and the definition excellent. My plan did not provide for any comparison differentially with a neighbouring star by micrometric measurement, and hence I only noticed the relation of the star to the sun and θ Cancri." It is difficult to understand how the observation can be explained, except by admitting the existence of an unknown body in the vicinity of the star, or by imputing to the deceased astronomer a want of *bona fides*, for which we do not believe there is the slightest excuse; he was too well known and respected to allow of such an imputation.

The solar eclipse of May 17, 1882, will afford the next opportunity of repeating observations of the kind made by Prof. Watson in 1878, but the duration of totality will nowhere exceed 1m. 48s., and in the most accessible portion of the central line will amount to 1m. 15s. only.

THE TRANSIT OF MERCURY, NOVEMBER 7, 1881.—With the positions of the Sun and Mercury given in the *Nautical Almanac* from Leverrier's Tables, and the diameters of those bodies obtained by the same astronomer from the discussion of former transits, the following will be the geocentric Greenwich times and the reduction-formulæ for the internal contacts during the transit of Mercury on November 7 in the present year:—

First internal contact, Nov. 7, 10h. 18m. 15s.·8 + [1·4205] $r \sin l$ − [1·5404] $r \cos l \cos (L + 55° 34'·2)$.

Last internal contact, Nov. 7, 15h. 35m. 28s.·2 + [0·9136] $r \sin l$ + [1·6302] $r \cos l \cos (L - 35° 23'·2)$.

Where r is the radius of the earth at the place, l its *geocentric* latitude, and L the longitude from Greenwich, reckoned towards the east. The quantities in square brackets are logarithms of seconds of time.

It will be seen that the transit will be invisible in this country, and will be best observed from the Australian observatories. At the Cape of Good Hope the sun will not rise till about four minutes after the second internal contact has taken place. At Madras he will be above the horizon before the middle of the transit, which ends there about 20h. 59m.

As an example of the use of the above formulæ we may compute the local mean time of first internal contact for the Observatory at Melbourne. The longitude of this observatory is 9h. 39m. 54s. 8 E., or in arc 144° 58′·7, and the geographical latitude is − 37° 49′·9. From Bessel's Table in the *Berliner Jahrbuch* for 1852, we find log. $r = 9{\cdot}9999$, and the reduction of latitude, 11′·1, so that $l = -\ 37° 38'·8$.

Constant	+1·4205	Constant +	55° 34′·2
r	9·9999	Long. ...	144° 58′·7

A NEW COMET.—The Smithsonian Institution telegraphs the discovery of a comet by Mr. Lewis Swift on the morning of the 2nd inst. in the constellation Andromeda; motion slow, southwards.

GEOGRAPHICAL NOTES

WE understand that the Council of the Geographical Society have recently voted a contribution of 100*l.* towards the expenses of the Palestine Exploration Fund's Expedition to Eastern Palestine.

THE May number of the Geographical Society's *Proceedings* contains Mr. James Stewart's paper on Lake Nyassa and the water-route to the lake-region of East Africa, with a map of the north end of Nyassa. A note afterwards given embodies recent information from Livingstonia as to a serious depression in the level of the lake, which threatens to make the south end, as well as the Upper Shiré, unnavigable, and by consequence detract very seriously from the value of this route. Col. Tanner's paper on Kafiristan is also given, with a map of that and the adjacent region. Some account is furnished of Dr. Junker's journey in the Nyam Nyam country from the traveller's letters to Dr. Schweinfurth and Signor Gessi. Reference is again made in the Geographical Notes to the late Capt. Wybrants' expedition to South-East Africa, but complete details of its disastrous ending are still wanting, which seems the more remarkable as the lamented leader died as far back as November 29, 1880. An interesting note deals with Dr. Kirk's recent visit to the Dar-es-Salaam district of East Africa, and it is also stated that the Rev. T. J. Comber is about to make another attempt to reach Stanley Pool by the Makuta route, while one of his companions will follow the line of the Congo. The remaining notes refer to Major J. Biddulph's work on the tribes of the Hindu Kush, and Père Desgodins' labours in the cause of geography on the eastern and southern frontier of Tibet.

AT the evening meeting of the Geographical Society on Monday next Mr. E. Whymper will read a paper describing the geographical results of his journey among the Andes of Ecuador.

THE new volume of the *Geographisches Jahrbuch* is of great value to scientific geography in its most comprehensive acceptation. Dr. Behm has been compelled to retire from the editorship, and is succeeded by Prof. H. Wagner of Göttingen, who, we have no doubt, will maintain the *Jahrbuch* at its previous high standard. The first part is devoted to the various geographical sciences. The first paper is by Prof. Zöppritz, "On the Present Standpoint of Physical Geography." This is followed by an account of recent researches in geographical meteorology by Dr. Haan; and papers on the Geographical Distribution of Animals and of Plants by Dr. Schwarda and Dr. Oscar Drade respectively. Prof. Bruhns summarises recent work in Europe in the measurement of degrees, and Herr Auwers gives the latitudes and longitudes of 144 astronomical observatories. Prof. F. v. Fritsch brings together recent investigations on the geographical distribution of geological formations all the world over; while Dr. v. Scherzer has his usual account of the world's commerce, and Dr. Gerland summarises recent advances in ethnological research. In the second part, which deals with general matters, Dr. Wagner has a thoughtful and useful article on the development of *Methodik* in geography; while, along with Herr Wichmann, he brings together a good deal of information on geographical societies, congresses, and journals. Thus it will be seen the new volume contains much matter of permanent interest.

WE have received Nos. 6, 7, and 8 (in one thick volume) of the *Bulletin* of the Union Géographique of the North of France. M. Leon Lacroix has a long paper describing a plan for the exploration of Central Africa, by the Wellé, a project we should much like to see carried out. M. Alf. Renouard, in a paper on the Geography of Flax, brings together much curious and useful information. Dr. Harmand's paper on the Races of Indo-China ought to interest ethnologists. Among the other contents are papers on the French in Indo-China, by M. Suerus; Syria in 1860, by M. Huberdeaux; and a note on the Isthmus of Panama, by M. V. Duburcq.

THE principal paper in the January number of the *Bulletin* of the Paris Geographical Society (just received) is one of much research, by M. Dutreuil de Rhins, on the routes between China and India.

THE *Mittheilungen* of the Vienna Geographical Society contain an account of a botanical excursion in the north of the Caucasus, by M. P. Muromtzoff, and a paper on the Floods of the Winter of 1880–81, by Baron Stefanovic von Vilovo.

UNDER the title of "Istruzioni Scientifiche dei Viaggiatori," the Italian Ministry of Agriculture, Industry, and Commerce have issued a very full and carefully compiled manual of information and instruction for travellers, edited by Signor Arturo Issel, with the collaboration of several specialists. The manual seems to us to combine the best features of all its predecessors in other languages, and ought to be of real service to all travellers who know Italian. It includes astronomy, meteorology, geography, and topography, deep-sea exploration, geology and palæontology, anthropology and ethnology, zoology, botany, and mineralogy. It is published under the auspices of the Italian Geographical Society.

HEFT 4 of Band ii. of the *Mittheilungen* of the German African Society contains communications from Dr. Büchner and Herr Flegel. The former has been doing a considerable amount of exploration between the capital of Muato Janvo's kingdom and the Congo, though his progress has been hindered by the usual African difficulties. His collections have been very numerous; unfortunately several boxes of them have been lost in the vessel in which they were being brought home, which was wrecked during the recent gales in the Channel. Herr Flegel has been doing some successful work on the lower and middle Niger.

PROF. GIUSEPPE DALLA VEDOVA has published the address he gave on the inauguration of the Chair of Geography at the University of Rome in November last. The subject is the Popular and the Scientific Conception of Geography. He shows that while the popular idea has its uses, the scientific conception is the only basis on which the subject can be studied with profit. He insists on the fact which has been frequently expounded in these pages, that geography has really become a sort of meeting-place for all the sciences, and that while topography may form the groundwork, it requires a knowledge of most of the physical and biological sciences to understand how the surface of the earth has reached its present condition.

DR. OSCAR LENZ has arrived in Berlin, where he has been lecturing on his journey across the Sahara to Timbuctoo.

AFTER all there seems to be little doubt that the news of the massacre of Col. Flatters and the other members of the Trans-Saharan Expedition is too true. Of course the project of a railway across the Sahara must be abandoned, in the meantime at least.

FROM *Les Missions Catholiques* we learn that news has at length been received respecting Père Law's expedition from Gubuluwayo, in Matabele Land, to Umzila's country, which was known to have met with some misfortune on the road. After passing the Insimbi Mountains the party reached the Great Sabi River, on the lower course of which we presume that Capt. Phipson-Wybrants died. The expedition journeyed, with their heavy waggon, along the left bank of the Sabi, meeting with country so difficult to traverse that in some parts they had to hew out of the rock a road for their waggon. Progress in this manner was terribly slow, and when that part of the Mashona country which owns some sort of allegiance to Umzila was reached, difficulties increased, as the natives did all they could to hinder their passage. Eventually on August 7, in a rugged pass where, surrounded by Mashonas, the missionaries were all doing their utmost to cut a road for the waggon, Père Wehl, by an accident not very clearly explained, got separated from his companions and was never seen again, though later news seems to have reached Gubuluwayo of his safety among a friendly tribe. Père Law and the rest of the party not unnaturally took fright at this, and leaving their waggon, escaped from their savage tormentors in the night. After about a fortnight's march they contrived to reach Umzila's kraal in a state of great exhaustion from fever and fatigue. They of course had to abandon almost all their property with the waggon, but further supplies have since been sent to them from Gubuluwayo.

PÈRE DEPELCHIN, the head of the mission station at Gubuluwayo, has been for some time absent on an expedition beyond the Zambesi, and from his long silence it was thought that he too must have met with some serious accident. He appears, however, to have reached in safety an out-station at Tati in Matabele Land, but no account of his adventures has yet been received.

MR. MCCALL, of the Livingstone (Congo) Inland Mission, is said to have formed a station at Manyanga, some 200 miles up the Congo, above the Yellala Falls, and he has no doubt about being able to reach Stanley Pool this year. The comparatively rapid progress thus made by following the right bank of the Congo will probably induce the Baptist Missionary Society's party at San Salvador to alter their tactics and follow the line of the river, instead of wasting their energies in fruitless attempts to make their way by land through the hostile Makuta towns to Makwekwe, on the left bank of the Congo, above Manyanga, and so on to Stanley Pool.

THE French Geographical Society held its annual meeting on Friday, April 29, when Admiral La Roncière le Noury was elected president. On the occasion of a proposal to erect a monument to Col. Flatters and his companions it was resolved to inscribe on tablets the names of all the martyrs of geography who have lost their lives in any exploration in which the French Geographical Society has been interested.

DR. O. F. VON MÖLLENDORFF has just published separately at Berlin (Reimer) two maps which have been drawn from his surveys by Dr. Kiepert for the Berlin Geographical Society's *Zeitschrift*. One is an original map of the hill-country north and west of Peking, while the other embodies routes in the Chinese province of "Dshy-li," and environs of Tientsin. Dr. Möllendorff, as we have before mentioned, claims to be an authority on the subject of the transliteration of Chinese sounds, but we doubt if many people in this country will recognise in "Dshy-li" the name of the metropolitan province (Chihli), and yet the maps are issued with English titles.

THE FUTURE DEVELOPMENT OF ELECTRICAL APPLIANCES[1]

THE lecturer began by referring to our obligations to laboratory workers and the necessity for a larger endowment of original research. The applied science of the future lies in-

[1] Abstract of a lecture delivered by Prof. John Perry at a meeting of the Society of Arts, March 24.

visible and small in the operations of men who work at pure chemistry and physics, and it is especially true of laboratory work in electricity that every day a man sees new lines of research opening up before him which his resources do not allow him to follow up.

In the applied science of electricity certain fixed laws tell us much about the future which is not generally known; and it is first necessary to become acquainted with these laws if we would speak of this future. By numerous experiments the lecturer showed that electricians are dealing with measurable things, and he gave in wall-sheets such information as seemed sufficient to give exact ideas in this matter to a popular audience. These wall-sheets had also been put in a printed form and circulated among the audience. The following is an example :—

WALL-SHEET II.—ELECTRICAL MAGNITUDES
(SOME RATHER APPROXIMATE)

Resistance of	
One yard of copper wire, one-eighth of an inch diameter	0·002 ohm.
One mile ordinary iron telegraph wire	10 to 20 ohms.
Some of our selenium cells	40 to 1,000,000
A good telegraph insulator	4,000,000,000,000
Electromotive force of	
	Volts.
A pair of copper-iron junctions at a difference of temperature of 1° Fahr. =	0·000,01
Contact of zinc and copper ... ... =	0·75
One Daniell's cell ... ... =	1·1
Mr. Latimer Clark's standard cell ... =	1·45
One of Dr. De La Rue's batteries ... =	11,000
Lightning flashes probably many millions of volts.	

Current measured by us in some experiments :—

Using electrometer ... ... =	almost infinitely small currents.
	Weber.
Using delicate galvanometer	= 0·000,000,000,040
Current received from Atlantic cable, when twenty-five words per minute are being sent	= 0·000,001
Current in ordinary land telegraph lines	= 0·003
Current from dynamo machine ...	= 5 to 100 Webers
In any circuit, *current* in webers ...	= *electromotive force* in volts ÷ *resistance* in ohms.

WALL-SHEET III.—RATE OF PRODUCTION OF HEAT CALCULATED IN THE SHAPE OF HORSE-POWER

In the whole of a circuit = *current* in webers × *electromotive force* in volts ÷ 746.

In any part of circuit = *current* in webers × *difference of potential* at the two ends of the part of the circuit in question ÷ 746.

Or, = square of current in webers × resistance of the part in ohms ÷ 746.

The distinction which must be made between *electricity* and *electrical energy* was dwelt upon. A miller does not merely speak of the quantity of water in his mill-dam; he has also to consider the height through which it can fall. A weight of one thousand pounds falling through a distance of one inch represents the same energy, that is, gives out the same amount of work in falling as one pound through one thousand inches. A mere statement then of the quantity of electricity given out by a machine is insufficient; it is also necessary to state what is the height or difference of potential through which it is falling. The quantity of electricity in a thunder-cloud is comparatively small, but the difference of potential through which this quantity passes when discharge occurs is exceedingly great. So it is with the two factors of the electrical energy developed by this glass machine. The quantity of electricity obtainable from this machine is comparatively small, but it is like a small quantity of water at an exceedingly great height, whereas in all these other machines we have, in the analogy of the miller, a very great quantity of water and a very small difference of level. I put this water analogy before you because you have all more or less exact notions about water, and because, within certain limits, the analogy is a very true one. I have traced it more fully in the wall-sheet. Of this and the other wall-sheets each of you possesses printed copies.

WALL-SHEET I.

We Want to Use Water.	*We Want to Use Electricity.*
1. Steam-pump burns coal and lifts water to a higher level.	1. Generator burns zinc, or uses mechanical power, and lifts electricity to a higher level or potential.
2. Energy available is, amount of water lifted × difference of level.	2. Energy available is, amount of electricity × difference of potential.
3. If we let all the water flow away through channel to lower level without doing work, its energy is all converted into heat because of frictional resistance of pipe or channel.	3. If we let all the electricity flow through a wire from one screw of our generator to the other without doing work, all the electrical energy is converted into heat because of resistance of wire.
4. If we let water work a hoist as well as flow through channels, less water flows than before, less power is wasted in friction.	4. If we let our electricity work a machine as well as flow through wires, less flows than before, less power is wasted through the resistance of the wire.
5. However long and narrow may be the channels, water may be brought from any distance, however great, to give out almost all its original energy to a hoist. This requires a great head and small quantity of water.	5. However long and thin the wires may be, electricity may be brought from any distance, however great, to give out almost all its original energy to a machine. This requires a great difference of potentials and a small current.

After showing, by passing currents from two large Gramme machines through certain resistances and lamps, that electrical energy may be sent to a distant place and there converted into heat and light, the methods taken at the City and Guilds of London Institute for simultaneously measuring mechanical work, currents of electricity, resistance, the candle-power of electric lamps, &c., were described, the dynamometers, photometers, &c., being exhibited, as well as diagrams showing their construction. Actual measurements were made of the strengths of currents and the candle-power of an electric light. Many of the contrivances in use were invented by the lecturer and his friend Prof. Ayrton.

The transmission of mechanical power to a distance through the agency of electricity was illustrated by a number of experiments; the driving of a lathe and other machines, and proof that the motor which gives out power at the distant place produces a back electromotive force opposed to that of the generator.

"Now what do these examples show you? They show that if I have a steam-engine in my back yard I can transmit power to various machines in my house, and if you were to measure the power given to these machines you would find it to be less than half of what the engine driving the outside electrical machine gives to it. Further, when we wanted to think of the heating of buildings and the boiling of water, it was all very well to speak of the conversion of electrical energy into heat, but now we find that not only do the two electrical machines get heated and give out heat, but heat is given out by our connecting-wires. We have then to consider our most important question. Electrical energy can be transmitted to a distance, and even to many thousands of miles, but can it be transformed at the distant place into mechanical or any other required form of energy, nearly equal in amount to what was supplied? Unfortunately I must say that hitherto the practical answer made to us by existing machines is 'No'; there is always a great waste due to the heat spoken of above. But fortunately we have faith in the measurements, of which I have already spoken, in the facts given us by Joule's experiments and formulated in ways we can understand. And these facts tell us that in electric machines of the future, and in their connecting-wires, there will be little heating, and therefore little loss. We shall, I believe, at no distant date, have great central stations, possibly situated at the bottom of coal-pits, where enormous steam-engines will drive enormous electric machines. We shall have wires laid along every street, tapped into every house, as gas-pipes are at present; we shall have the quantity of electricity used in each house registered, as gas is at present, and it will be passed through little electric machines to drive machinery, to produce ventilation, to replace stoves and fires, to work apple-parers, and mangles, and barbers' brushes,

among other things, as well as to give everybody an electric light.

"Probably you think it very strange that I should show you the inefficiency of electric transmission of energy, and then make this very bold assertion. Well, the fact is that the ordinary electrical machines in use have not been constructed with a view to economy. They have been constructed to show that brilliant lights and considerable power may be produced from small machines. They have, at a comparatively small cost, attracted attention to the fact that electricity is an important agency. In so far they have done well; but on the other hand they gave rise to the well-known assumption that 50 per cent. of the mechanical power given to the generator was the maximum amount which could be taken from the motor. The true solution of the problem of transmission of power was, I believe, first given by Prof. Ayrton in his Sheffield British Association lecture. It had been supposed that to transmit the power of Niagara Falls to New York a copper cable of enormous thickness would be needed. Mr. Ayrton showed that the whole power might be transmitted by a fine copper wire, if it could only be sufficiently well insulated. He also showed that instead of a limiting efficiency of 50 per cent., the one thing preventing our receiving the whole of our power, is the mechanical friction which occurs in the machines. He showed, in fact, how to get rid of electrical friction. I will briefly give you our reasons. A machine at Niagara receives mechanical power, and generates electricity. Call this the generator, and remember that Wall-sheet III. teaches us that the mechanical power is proportional to the electromotive force produced in the generator, multiplied into the current which is actually allowed to flow. Let there be wires to another electric machine in New York, which will receive electricity, and give out mechanical work, as this machine does here. Now I showed you a little while ago that this machine, which may be called the motor, produces a back electromotive force, and the mechanical power given out is proportional to the back electromotive force multiplied into the current. The current, which is of course the same at Niagara as at New York, is proportional to the difference of the two electromotive forces, and the heat wasted is proportional to the square of the current. You see then, from Wall-sheet III., that we have the simple proportion—power utilised is to power wasted, as the back electromotive force of the motor is to the difference between electromotive forces of generator and motor. This reason is very shortly and yet very exactly given in Wall-sheet IV., a printed copy of which you all hold in your hands."

WALL-SHEET IV.

Let electromotive force of generator be E; of motor F. Let total resistance of circuit be R. Then if we call P the horse-power received by the generator at Niagara. Q the horse-power given out by motor at New York, that is, utilised. H the horse-power wasted as heat in machines and circuit. C the current flowing through the circuit.

$$C = \frac{E - F}{R}$$

$$P = \frac{E\,(E - F)}{746\,R}$$

$$Q = \frac{F\,(E - F)}{746\,R}$$

$$H = \frac{(E - F)^2}{746\,R}$$

$$Q : H :: F : E - F.$$

"To put it more shortly still, the power wasted is proportional to the square of the current flowing, whereas the power utilised is proportional to the current, and also to the electromotive force of the motor. The greater, then, we make the electromotive forces, the less is the loss of power in the whole operation. Perhaps you will see this better from the water analogy. A small quantity of water flowing through a water-main may convey a large amount of energy, if it only has sufficient head. The frictional loss of power is independent of the head, but depends very much on the quantity of water. In the model before you is the water analogy. Here is a reservoir, which I shall call A, kept filled with water by a steam pump, which draws the water from the sea-level, which I shall call K. Water flows from reservoir A to distant reservoir B, where it drives a turbine giving out work due to its head B K. The current from A to B, through the communicating pipe, is the same always, so long as A and B are at the same difference of level, and therefore the frictional loss of energy is always the same, whereas the work utilised from B, by driving the turbine, increases proportionally to the height of B above sea-level. The result, then, to which the above laws led us was that for the future development of the transmission and distribution of electric energy it will be necessary to use electric machines of great electromotive force. Indeed so important must this principle become that we believe there is a future in this direction for the employment of even plate electrical machines, such as that of Holtz."

Then followed a discussion of methods of obtaining great electromotive force. Mr. Perry's own ways of carrying out these ideas are shown in his own dynamo-machine, which is large, has great speed, has no iron in its movable part, and has a commutator of small frictional resistance. Electric lighting and heating, telephones, and electric railways of the future were all spoken of as illustrations of the transmission of energy by electrical means, and as such they must be governed by the above principle.

It was then shown experimentally that electrical energy may be stored up in considerable quantities in an available form for future use, and the bearing of this fact on the future utilisation of great but variable natural sources of power, such as the wind and tide, was dwelt upon.

The remainder of the lecture was devoted to the importance of the principle of recurrent effects; one illustration was given as follows:—"If I very much alter the magnetic field in this telephone, by bringing a powerful magnet near it, with great care in listening I hear the faintest sigh, due to the diaphragm settling itself into a new position, its vibrations dying away as it does so; and if I brought a small magnet near, I should hear nothing. And yet the change of magnetism which produces the loud telephonic effects which we listen to is almost infinitely smaller. Why is this? It is due to the rapid recurrence of the effects. Now you are all aware of the importance of the telephone as a method of communication; I believe that a much greater importance is in store for it as a laboratory appliance."

The photophone and the method by means of which Messrs. Ayrton and Perry determined the index of refraction of ebonite, finding its square to be roughly the same as the mean value of its measured specific inductive capacities: the use of a powerful sub-marine source of musical sound as a coast-warning, which might be heard in a ship well above all other sounds, and the experiments which have been made by the lecturer and his colleague in this direction: these and other matters were discussed as examples of the use of the principle of recurrent effects. The lecture concluded by an account illustrated by experiments of Mr. Edward Bright's method of de-electrifying woollen yarn, and of Messrs. Ayrton and Perry's plan for seeing by electricity what is occurring at a distant place. A selenium cell moving over an image at, say, York, gave corresponding light and shade to corresponding parts of a screen at, say, London. Mr. Perry's York image was very simple, being a series of black, grey, and white squares, which were faithfully reproduced on the distant screen.

MECHANICAL RESEARCH

IT will be remembered that some time ago the Institution of Mechanical Engineers appointed a Committee to examine into three selected questions of research in matters pertaining to their profession. These researches are still in progress, but preliminary reports have been issued by the Committee, of which we propose to give a brief account.

The Hardening and Tempering of Steel.—One or two letters on this subject have lately appeared in our columns, and allusion has been made to the report by Mr. Wm. Anderson, presented to the Committee who were appointed specially to investigate this difficult question. Mr. Anderson's report, which contains much useful information in a comparatively small compass, is itself too long for our pages. We therefore give the following *résumé* of the question, taking Mr. Anderson's report as our basis:—

Whilst the theory of this subject is in a very vague and uncertain condition, the facts are exceedingly well known, and are daily applied in almost every department of arts and manufactures. Wherever steel tools are used it is necessary that they should be hardened and tempered; since the ordinary tool-steel, as supplied chiefly from Sheffield, is too soft for cutting and

abrading purposes. It is known however that if a piece of this steel be heated, and then suddenly cooled (generally in a bath of water or oil) it becomes much harder, not only on the surface, but throughout, provided its thickness be not excessive. The greater the range of this cooling (in other words, the difference between the temperatures of the steel and the bath at the first moment of "quenching") the more intense is the hardening, but at the same time the greater the brittleness of the piece. Hence it is always desirable that the range of cooling should be as small as is consistent with the steel acquiring that degree of hardness which is essential for the work it has to do. This condition is secured by the further operation of tempering. In this process the steel is first hardened to excess by rapid cooling, then re-heated with great care to a certain temperature corresponding to the purpose for which it is intended, and then quenched again from that temperature. The particular point at which to stop the re-heating is recognised by one particular hue in what are called "the colours of tempering," *i.e.* a fixed range of colours, commencing with pale yellow and ending with dark blue, which the steel is always seen to assume in succession as its temperature gradually rises. Thus, if the article in question be a sword it is heated to a bright blue; if it be a cold chisel it is stopped at a brownish orange.

The various attempts to explain these singular facts (at least on the part of French and English metallurgists) are set forth in the Committee's Report. In the first place it seems now to be generally held that pure steel is a compound of iron and carbon only, and that these two elements exist, not in a state of chemical combination (forming some definite carburet of iron), but of intimate mechanical mixture, such as chemists call by the name of "solution." The question next arises, What is the exact condition of each of these independent elements. In the case of very soft, or "grey," cast-iron, it is known that the carbon is not wholly in solution, but occurs partly in molecules of pure graphite. Following this hint M. Jullien has advanced the theory that molten cast-iron, or molten steel, is a solution of liquid carbon in liquid iron; that under slow cooling part of the carbon separates as graphite, while the remainder continues in solution; but that with rapid cooling this separation does not take place, and the whole of the carbon crystallises, forming, when cool, a "solution" of crystallised carbon in amorphous iron. This view of the difference between hard and soft cast-iron, or hard and soft steel, is accepted by Caron, Åkerman, and others, partly on the ground that hardened steel dissolves completely in hydrochloric acid, while the same steel, after annealing, will leave a residue of insoluble carbon. Jullien, however, goes beyond this, and would explain the whole phenomena of hardening on the same principle. He holds that carbon liquefies in presence of red-hot iron, and is absorbed by it; that if the mixture is cooled slowly the carbon remains amorphous, but if cooled quickly the carbon crystallises in the diamond form; and thus hard steel is iron set in a matrix of diamond. This theory, though ingeniously supported, labours under the difficulty that the liquefaction of carbon has never been otherwise achieved; and also that it gives no explanation whatever of the phenomena of tempering, especially the characteristic colours. On the other hand, Barba and Åkerman hold that the hardening of steel is due to the severe compression produced in the outer layers by the contraction in rapid cooling; this compression at once retaining a greater proportion of carbon in solution, and rendering the whole mass more physically dense and compact. But the Report points out that the outside layers, which are the hardest, are brought into a state of tension, not compression, owing to their inability to contract over the hotter mass inside.

For these reasons the Committee have rejected both these theories, and propose one of their own, due apparently to Mr. William Anderson, but suggested by the experiments of Edison on platinum wire, an account of which appeared in NATURE, vol. xx. p. 545. They refer to the generally-accepted fact that ordinary steel contains a certain proportion of occluded gases (consisting, according to Müller, of hydrogen, nitrogen, and carbonic oxide). They suggest that the application of heat causes these gases to be expelled through minute fissures which open in the steel, as they opened, according to Edison, in the platinum wire observed by him; and that sudden cooling prevents the re-absorption of what has been expelled, perhaps actually tends to expel the remainder. By the loss of these gases the metal becomes denser and harder than before. If the metal be now expanded by gentle heating, the fissures open, re-absorption begins; and the various changes which the surface undergoes during this process are marked by the succession of colours which are characteristic of tempering.[1] The Committee propose to make a series of experiments to test the truth of this theory, which is certainly ingenious, and if confirmed would go far to remove the difficulties which beset this important subject.

Form of Riveted Joints.—The second Report is written by Prof. W. C. Unwin, of Cooper's Hill, and is on "the best form of riveted joints to resist strain in iron or steel, or in combination." It may be well to explain that by a "riveted joint" is meant the mode of fastening together the strips, or plates, out of which boilers, tanks, girders, and other structures in wrought iron or steel are built up. This mode in its simplest form is as follows:—A row of holes is punched or drilled along the edge of the two plates to be united, and these edges are then made to lap over each other so that each hole in one plate comes fair with a hole in the other. A red-hot rivet (that is a pin with a rounded head) is then passed through both holes, and the end is flattened down by hammering or pressure, so as to form a second head. The two plates are thus pinned together by the rivets, and so long as these remain entire they cannot be separated without tearing across. Such a joint is called a "single-riveted lap-joint." It is obvious that the plate must be greatly weakened by the piercing of the holes; and as a matter of fact it appears that such joints cannot be arranged to give more than about half the strength of the solid plate. To increase this "proportion of strength," as it is termed, the rivets are sometimes arranged in two or three rows, and of course more widely spaced in each row; or the edges of the two plates are simply brought up against each other and secured by either one or two "cover-strips" fitting over and riveted to both.

Each of these forms demands a separate investigation in order to fix its design. Thus a single-riveted lap-joint under a tensile stress may fail in any one of the following ways: (1) the rivet may cut into the plate, enlarging and injuring the hole; (2) the plate may cut into the rivet, and finally shear it off; (3) the part of the plate between the rivet and the edge may break through, allowing the rivet to come away from the plate; (4) the plate may simply tear across along the line of rivets. It is clear that in a perfect joint the dimensions must be such that the resistance to each of these modes of fracture should be the same, and should have its greatest possible value. This could be easily arranged if the absolute resistance of the material to these various forms of stress were accurately known. But the values of these resistances are of course very different for steel and for iron; they also vary considerably, whether in steel or iron, according to the quality, and to some extent according to the thickness. Hence experiments on these values become absolutely necessary before any correct design can be made out.

The course which such experiments should take is fairly sketched out by the author of the Report now before us. A good and uniform quality of iron or steel, as the case may be, should first be selected, both for plates and rivets. The resistance of this material to the various forms of stress should then be carefully ascertained by experiments made both with simple bars or plates, and also with actual riveted joints, so designed that they shall be certain to fail in one particular way. These constants once settled, it is easy to calculate for any description of joint the dimensions which will give the highest proportion of strength. A joint should then, and not till then, be prepared, having exactly these dimensions, and a few others having dimensions varying slightly from these in each direction. If, on testing, the first joint proves to gives the highest breaking strain of the set, the correctness of the whole investigation will be established.

Unfortunately the method thus sketched out has not hitherto been adopted. The immense practical importance of the subject (for the money expended yearly on riveted structures may be counted by millions) has indeed brought forward a host of experimenters; and the mere classification and abstracting of their results occupies no less than sixty octavo pages of this Report. But almost without exception they seem to have begun at the wrong end, *i.e.* they started with making a riveted joint of what they chose to consider to be the best design, and then pulled it asunder. In addition, scarcely any of their experiments have been made with the care and accuracy, or on the scale, which the subject demanded. In fact it is not going too far to say that 90 per cent. of these experiments are only injurious, as

[1] The Report supposes that the colours of tempering are due to diffraction, not to interference: this does not seem to be in accordance with the facts, but it also does not seem to be absolutely required by the explanation.

cumbering the ground, and that the remaining 10 per cent., if useful, are very imperfect. One instance of the evil done by such means will suffice. Sir Wm. Fairbairn, to whom is due the credit of being the earliest labourer in this field, experimented on certain single- and double-riveted joints, and found that the "proportion of strength" in the case of the former was 56 per cent., and in the latter 70 per cent. of the solid plate. These figures, which of course applied only to the particular designs tested, have been repeated in almost all manuals of engineering as if they were universally true; disregarding the obvious fact that a double-riveted joint could be made just as weak as a single-riveted one, by simply spacing the holes in the outside row at the same distance.

The Committee wisely determined to throw aside the voluminous labours of their predecessors, and begin *de novo* a connected series of experiments, based on the true and scientific method described above. We cannot find space to consider the many collateral points with which these experiments will have to deal, much less to give any account of the results which they are to supersede. These, as embodied in this Report, will remain a singular instance of the lamentable waste of money so continually incurred in engineering experiments. There can be little doubt that less than a tenth of this money, if applied on the scientific and proper method, would have set the whole question long ago at rest, and would now be saving the world, through increased economy of construction, many hundreds per annum for every pound so expended.

Friction.—The last of the three subjects under consideration is that of Friction at High Velocities, the Report on which has been prepared by Prof. Kennedy, of University College, London. This subject offers a curious instance of the influence exercised by a distinguished experimenter, and how his conclusions are pushed, by those who blindly follow his guidance, much further than he himself would attempt to go. About fifty years ago the late General Morin made an important series of experiments, from which the well-known "Laws of Friction" were deduced. One of these laws is that the friction between solid bodies in motion, or dynamical friction, is independent of the velocity. It was overlooked, by those who announced this law, that the experiments were only conducted with certain substances under small pressures and at moderate speeds. General Morin himself, in an interesting letter published in the present Report, expressly states that he had himself always regarded his results, "not as mathematical laws, but as close approximations to the truth *within the limits of the data of the experiments themselves.*" Unfortunately others did not imitate this caution: they asserted everywhere that the law was universal, and by many it is asserted to be so still.

That it is not universal has however been sufficiently proved. At the time of the launch of the *Great Eastern* the late Mr. Froude showed, by experiments on a large scale, that the friction of a vessel on the launching-ways decreased rapidly as the velocity increased. In 1851 Poirée and Bochet showed that the coefficient of friction of railway wheels sliding on rails diminished very rapidly with increase of speed (between limits of 900 and 3600 feet per minute). Recently Capt. Douglas Galton and Mr. Westinghouse made a long series of experiments on the friction of railway-brakes (cast-iron blocks on steel tyres), and their results showed a marked decrease of friction, with increase of speed, within the very large range of 400 to 5300 feet per minute. Prof. Kimball has made experiments at much lower speeds (about 1 to 100 feet per minute), both with pieces of wood and with wrought-iron spindles in cast-iron bearings; and he also finds a rapid decrease of friction with increase of speed. At the lowest possible speeds (0·012 to 0·6 feet per minute) Prof. Fleeming Jenkin finds a similar decrease, pointing to the supposition that the change from statical to dynamical friction is not sudden, but continuous. Lastly, Prof R. H. Thurston has made an elaborate set of experiments on the frictional resistance of lubricated bearings. He arrives at the conclusion that for cool and well-lubricated bearings the coefficient of friction decreases up to a speed of about 100 feet per minute, and afterwards increases with the speed approximately as its fifth root. The details of these experiments do not seem to have been published, so that it is not certain how far this curious result may be taken to hold.

It will be seen that none of these various experiments confirm the universal law deduced from Morin's results, viz. that dynamical friction is independent of velocity. On the contrary, it may be taken as proved for *unlubricated* surfaces (such as railway brakes) that the coefficient of friction diminishes rapidly with increase of velocity; although the exact law of variation and its relation to the pressure on the surfaces is not fully determined. With *lubricated* surfaces the same fact may be assumed to be true at speeds up to 100 feet per minute; but above this, if we accept Prof. Thurston's results, the result is the opposite. It seems clear that the question is ripe for further investigation, which might take the form, first of repeating and extending Thurston's experiments with lubricants, and secondly of ascertaining the law of variation with unlubricated surfaces more exactly than could be done by the aid of the experiments hitherto carried out.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—At the Downing College Examination in June, 1881, one Foundation Scholarship of the annual value of 80*l.* will be thrown open to all members of the University who have not kept more than six terms. The subjects of this Examination will be Chemistry (Theoretical and Practical), Physics (Heat, Electricity, and Magnetism), Comparative Anatomy, Physiology, and Botany. The Examinations for Minor Scholarships, which are open to all persons who have not entered at any college in the University or who have not resided one entire term in any such college, will be held in Downing College on Tuesday, May 31, and three following days. Further information will be given by Mr. J. Perkins or by the Rev. J. C. Saunders, tutors of the College.

AT a special meeting of the Fellows of Gonville and Caius College, held on the 30th ult., Dr. Paget, F.R.S., Regius Professor of Physic in the University, and Mr. Pattison Muir, Hon. M.A. (Cantab.), were elected Fellows of the Society. Dr. Paget was formerly a Fellow of Caius College.

OXFORD.—In addition to the courses of lectures in Natural Science enumerated last week, the following courses will be held during this term in the University Museum:—Prof. Price will lecture on physical optics, and Prof. Westwood will lecture on the orders of the Arthropoda. In the absence of Prof. Rolleston, who is abroad on account of ill-health, Mr. Jackson will form classes for general catechetical instruction, while classes will be formed by Mr. Robertson for practical microscopy, and by Mr. Thomas for the study of the developing chick.

At the Botanical Gardens Prof. Lawson will lecture on elementary botany (development), and will continue his course on the dissection of plants.

In the Geological Department under Prof. Prestwich, lectures will be given on some of the secondary and quaternary strata. The Professor will have excursions to inspect the sections of the several formations around Oxford, commencing on Saturday, April 30, and to be continued through May. On each preceding Friday he will lecture on the subject of the following Saturday's excursion, or on some other subject of which notice will be previously given. Notice will also be given in the Gazette of the preceding week, and in the Museum, of the places to be visited, hours of meeting, &c.

In a congregation holden on Tuesday, May 3, the proposal to allow selected candidates for the Indian Civil Service to obtain the B.A. degree after two years' residence, was thrown out. An amendment to excuse selected candidates from responsions only was carried by 63 votes to 49.

THE scheme for the establishment of a University College in Liverpool is now almost matured, and it is expected that the College will open for its first session in October next. The donations have reached the sum of 100,000*l.*, and the task of drafting a constitution for the College is now being performed by a special committee. The Earl of Derby has accepted the office of president, the vice-presidents being Mr. Christopher Bushell and Mr. William Rathbone, M.P.

SCIENTIFIC SERIALS

Journal de Physique, April.—Theory of machines with alternating currents, by M. Joubert.—On radiophony (second memoir), by M. Mercadier.—Application of Talbot's fringes to determination of the refractive indices of liquids, by M. Hurion.—Apparatus for projecting image at any distance with a variable enlargement, by M. Crova.—Strong and constant voltaic pile, furnishing residues capable of regeneration by electrolysis, by M. Reynier.

Reale Istituto Lombardo di Scienze e Lettere, Rendiconti, vol. xiv. fasc. vi.—On Chætognatha, by Dr. Grassi.—On the stratigraphical position of the phyllitic zone of Rotzo, and the marine limestones which comprehend it, by S. Taranelli.—On a Cremonian quadratic correspondence between the elements of two ruled spaces, by S. Archieri.—The last introduction of fishes into our lakes, by Prof. Pavesi.—On a freshwater sponge new to Italy, by the same.

SOCIETIES AND ACADEMIES

LONDON

Photographic Society, April 12.—J. Glaisher, F.R.S., president, in the chair.—The following papers were read:—On a Swiss tour with gelatine plates, by W. Dillworth Howard.—On art and photography, suggestions for bringing them into closer connection, by H. B. Berkeley.—On the natural camera, and on uncorrected lenses in photography, by Capt. Abney, R.E., F.R.S. This paper described the natural camera as being the means of taking a photograph without an optical glass—a pin-hole producing the picture, although at a long focus—also that an uncorrected or non-achromatic lens, say an ordinary spectacle lens, if its aperture be reduced to one-fifth of an inch, would bring the wave-lengths of all colours into one perfect focus, but which, being very long, would necessitate prolonged exposures; at the same time this could be met by the use of the modern rapid gelatine plate.

Victoria (Philosophical) Institute, May 2.—A paper upon philosophy as advocated by Mr. Herbert Spencer was read by the Rev. W. Ground. The aim of the paper was to show that the philosophy in question is hopelessly illogical, the "analysis" in direct contradiction to the "synthesis."

GÖTTINGEN

Royal Society of Sciences, January 8.—On a proposition of the maintenance of the algebraic relation between the integrals of various differential equations and their differential quotients, by Herr Königsberger.—Report on the polyclinic for ear diseases, by Dr. Bürkner.—On the motion of an electric particle in a homogeneous magnetic field and the negative electric glow, by Herr Riecke.—On the quantity of electricity furnished by an influence-machine of the second kind and its relation to moisture, by the same.—Measurement of the force exerted by earth-magnetism on a linear current conductor capable of rotation, by the same.

February 5.—Influence of heat on the optical properties of boracite, by Herr Klein.—On electrical shadows (third paper), by Herr Holtz.—New representation of spherical functions and related functions by determinants, by Herr Henn.—Remarks on a memoir, by Herr Warburg, on some actions of magnetic coercive force, by Herr Fromme.—Observations in the magnetic observatory, by Herr Schering.

March 5.—On the irreducibility of differential equations, by Herr Königsberger.—Contributions to a knowledge of the optical properties of analcim, by Herr Ben Saude.

PARIS

Academy of Sciences, April 25.—M. Wurtz in the chair.—The following papers were read:—On a question of ancient metrology; origin of the English mile, by M. Faye. He inquires into the error (long current) of supposing the mile equivalent in length to a terrestrial arc of one minute. The mile has been probably deduced from Ptolemy's measure, and the error of one-sixth seems to arise from the English geographers having supposed that Ptolemy used the Greek foot, which Eratosthenes used 400 years before, whereas he used the Phileterian foot, which is about 0·36m., the earlier one being 0·27m. Eratosthenes counted 700 stadia to a degree; Ptolemy only about 500.—Examination of materials from the vitrified forts of Craig Phadrick, near Inverness (Scotland), and Hartmannswillerkoff (Upper Alsace), by M. Daubrée. Like the forts in France, that at Craig Phadrick must have undergone heat intense enough for the mica to entirely disappear and the felspar to be in great part fused. The minerals produced at cost of the mica and felspar present evident similarities. The Alsace fort seems to have been composed of brown porphyry, but the crystalline products of heat are similar to those in the other case. The ingenious method of heating was probably transported, not invented independently in different countries. The phenomena elucidate metamorphism.—Meteorite which fell at Louans (Indre-et-Loire) on January 25, 1845, and the fall of which was not published, by M. Daubrée.—Researches on piperidine, by M. Hofmann.—Nodule of chromite in the interior of the meteoric iron of Cohahuila (Mexico), by Prof. Lawrence Smith. He obtained, on analysis, oxide of chromium 62·61, ferrous oxide 33·82. While chromite has long been known in association with meteoric stones, the form of its occurrence here is new. The meteorite contained distinct nodules of two chromiferous minerals.—Observations on phenomena of absorption in lower vegetable organisms, by M. Syrodot. Studying Batrachospermeæ, he has found the organs of absorption to present parallel phases to those better known in the higher groups.—M. Sire presented an instrument for demonstrating Foucault's law of the apparent deviation of the pendulum's plane of oscillation. The apparatus may be used in any latitude.—General theory of transmissions by metallic cables; practical rules, by M. Leauté. The author determines, *inter alia*, the coefficient of working (*fonctionnement*) in telodynamic transmissions, a coefficient which fixes the manner in which a cable behaves under a variation in the force exerted. The idea of equivalence of two transmissions as to working is thus reached. The limits of transmission of force by cables are investigated.—On the essence of licari kanali, or essence of female rosewood, by M. Morin. The composition of this essence from French Guyana appears to be identical with that of Borneo camphor.—On the winter-egg of phylloxera, by M. Mayet. About Montpellier the hatching of the egg has occurred during the whole month of April, and even in the end of March.—Results obtained in phylloxerised vines by a mixed treatment with sulphide of carbon and sulphocarbonate of potassium, by M. Laugier.—M. Faye, presenting the first volume of *Annales de l'Observatoire de Toulouse*, edited by M. Baillaud, said it marked a new era in the history of the provincial observatories, great activity being indicated. The researches of M. Tisserand (predecessor of M. Baillaud) on Saturn's satellites are given. M. Perrotin works out the theory of Vesta; while the zodiacal light, the eclipses of Jupiter's satellites, Saturn's rings, &c., are also studied.—On a class of linear differential equations with doubly periodic coefficients, by M. Appell.—Normal production of three systems of fringes of rectilineal rays, by M. Croullebois.—Causes of disturbance of telephonic transmissions, by M. Gaiffe. Two rods from the same piece of steel (capable of being strongly polarised without being tempered) were placed in a telephone circuit, one of them being first magnetised as much as possible. Striking them similarly produced strong currents from the magnetised rod, but very little current from the other.—On the renal origin of nefrogymase, by MM. Bechamp and Baltus.—On the absorption of mineral waters by the cutaneous surface, by M. Champouillon. The absorption of iron and manganese from the waters of Luxeuil was proved in examination of the urine. It is only after a period of mineral saturation that the minerals appear in the urine.—Remarks on the anatomy of pyrosoma, by M. Joliet.

THE LEPIDOPTERA OF SWITZERLAND

Die Lepidopteren der Schweiz. Von Prof. Dr. Heinrich Frey. 8vo. Pp. xxvi. and 454. (Leipzig: Engelmann, 1880.)

"IN the evening of a busy life I hand over for publication a book which, for a generation, has been suspended before my mind as an object to be attained. When in the summer of 1849, in the sunny days of youth, I, an indefatigable traveller, and passionate lover of *Lepidoptera*, for the first time traversed our glorious country in an extended sense, the idea of a Lepidopterous Fauna of Switzerland was conceived." In this manner the author (who is Professor of Pathology in the Polytechnic of Zürich) commences his introductory remarks. It may be well to state here that Dr. Frey is a Swiss only by adoption (we believe a native of Frankfort on the Main); and this will explain why it was not until 1849 that any extended journey in Switzerland had been made by him. His writings on Swiss *Lepidoptera* are familiar to all European students of the order. Many of these are monographic on special genera or groups, chiefly of the *Micro-Lepidoptera*, and in 1856 a volume of 430 pages—"Die Tineen und Pterophoriden der Schweiz" (a descriptive work)—appeared from his pen. To English readers his short, but very suggestive, paper on the "Tineæ of the Higher Alps," published in the *Entomologists' Annual* for 1858, can scarcely be forgotten. Now, "in the evening of life," as he terms it, he comes before the entomological public with his *magnum opus*. We heartily congratulate him thereupon.

It will readily be understood, from the fact of the work consisting only of one volume, and including therein *all* the Swiss species, that it is not descriptive, outside the very few new species or varieties mentioned in it. It is a carefully compiled catalogue, but very different from a bare dry list of names. To each species is appended a certain amount (not complete) of synonymy, indications of the food-plants of the larvæ, the time of appearance of the imago, and, what is most useful, a carefully analysed list of localities, with special regard to altitude, the latter being of great importance and value in treating of a fauna such as that of Switzerland. More than this, there are copious notes on the numerous varieties into which many species run, not only as concerns influences that locality may exercise in the country itself, but also in connection with the forms of the same species occurring in other parts of Europe.

Our author is strongly conservative in some of his views. He hesitates at species-splitting, unless there appear to be the strongest reasons for such a course. He almost snubs the innovations in Staudinger and Wocke's last European Catalogue (adopting however the sequence) by not accepting their changed nomenclature for the most part, but (for the sake of convenience and identification) placing the "restored" names between brackets.

We cannot presume to give an analysis of individual species and their distribution horizontally or vertically. This is everywhere carefully worked out, and more especially in the butterflies. 2508 species are recognised as Swiss, viz., 171 *Rhopalocera* (or butterflies), 61 *Sphingidæ*, 170 *Bombycidæ*, 439 *Noctuidæ*, 375 *Geometridæ*, 191 *Pyralidæ* and *Crambidæ*, 334 *Tortricidæ*, 727 *Tineina*, 35 *Pterophoridæ*, and 5 *Alucitæ*. If varieties (by some considered species) be added, the total is raised to 2829, the butterflies alone claiming 65 of these forms. In the higher groups the author has derived very great assistance from previous writers, or from the somewhat numerous collectors. But when we come to the *Tineina*, near the end of the work, all this is changed; whole pages, including many species on each, giving only one or two localities for each species, and "Frey" as the sole observer, a striking proof of the neglect under which those minute but intensely interesting forms suffer.

Switzerland attracts tourists from all parts of the world; many of these are entomologists who derive vastly increased pleasure and much profit by collecting insects; many of them publish accounts of the results of their excursions. We think the author might have added to his local information by consulting more of the scattered lists published by foreigners, and more especially many such that have of late appeared in English journals.

Very interesting are the copious introductory observations on the physical features of the country. A table gives thermometrical observations for twenty-six stations, showing a mean temperature ranging from + 12°58 Centigrade at Bellinzona (729 feet) to − 0°19 at the Julier Pass (7040 feet); of greatest cold from − 6°8 at Bellinzona to − 24°7 at Davos; of greatest heat from + 33°1 at Lugano to + 17°6 at the St. Bernhard Hospice. A copious analysis of the vertical range of vegetation, especially of certain trees, is given in connection with *Lepidoptera*. Conifers extend to over 7800 feet (it should be remembered that Paris feet are always intended; thus in English the heights would be seemingly greater) in the Southern Alps. At the Albula Pass (7120 feet) 152 species of *Lepidoptera* were noticed by the author, 44 of which were butterflies. About 8500 feet must be considered the limit for *Lepidoptera*, excluding occasional individuals carried higher by the winds. In a lengthened analysis the author does not lose sight of the probable origin of the Swiss fauna. Whilst showing indications of adoption of the glacial theory, he scarcely commits himself to an opinion, and prefers to give the facts, leaving it to others to build theories thereupon. A most instructive chapter is formed by an analysis of the following headings:—(1) species of the high Alps which occur unchanged in the high north and in other European mountain-ranges; (2) species which, living in the high Alps and the north, show but little change; (3) such as undergo greater change in the north and in other mountain-ranges outside Switzerland; (4) those that occur only in the Alps and in the Arctic Zone; (5) darker coloration in Alpine regions; (6) species introduced from the south. The introduction ends with five pages of about 470 Swiss localities, in double columns, with the altitudes.

The whole of this introductory portion cannot but prove fascinating to all who have visited the Alps, or have had occasion to study the insects of high latitudes. The time is fast approaching when multitudes of our countrymen

will be spreading themselves over the length and breadth, or the height and depth, of Switzerland. Many of these will be naturalists more or less acquainted with the Alpine insect fauna. To those who have already made its intimate acquaintance and are competent to distinguish the majority of the species in the field, this work will prove invaluable for consultation on the spot; to those who leave the determination of their materials until arriving home it will add interest to a not otherwise always enjoyable occupation:

In these latter remarks we have endeavoured to make it attractive to the numerous naturalists who are more or less amateurs. But its claims for careful study by those who are working at geographical distribution as a special branch of science, and at the philosophical speculations that such studies give rise to, are indisputable, and cannot be neglected. R. McLACHLAN

WORKS OF JAMES MACCULLAGH

The Collected Works of James MacCullagh. Edited by Professors Jellett and Haughton. Dublin University Press Series. (Dublin: Hodges, Figgis, and Co.; London: Longmans, Green, and Co., 1880.)

THE admirable practice of building a monument to departed men of science from the original works they have left behind them is steadily gaining ground, and is now indeed almost the rule. The collected works of Green, Rankine, Wheatstone, Cavendish, Graham, and Clifford have been comparatively recently published; those of Maxwell are being edited.

When the papers republished have been written many years the judgment of editors must be severely exercised; the temptation to point out the relation of the work of the original author to subsequent discovery is great, but the difficulty of deciding how much to add is greater. The late Prof. Maxwell in his edition of Cavendish added much of his own, thereby increasing manyfold the value and interest of the book, and at the same time more clearly exhibiting the penetration and genius of Cavendish. In the volume before us little of annotation and nothing of criticism is added, the work is left to speak for itself.

Nearly two-thirds of the book is occupied by the first part, containing the papers on Physical Optics. These are twenty-three in number. The first four deal with the geometrical treatment of Fresnel's theory of biaxal crystals. Unfortunately MacCullagh failed to perceive, or at least to point out clearly, the remarkable experiment of conical refraction, so soon after predicted by Hamilton and verified experimentally by Lloyd.

The method of the sixth paper, on the "Laws of Reflection from Metals," is characteristic, as we find a somewhat similar treatment of the theory of transmission of light in quartz and to some extent in the dynamical theory of double refraction. There is no pretence to a firm foundation on mechanical principles. A formula is assumed, the physical meaning of which is not apparent, and the deductions from that formula are interpreted. Fresnel's formulæ for the intensities of the reflected and refracted rays in the case of an ordinary transparent medium are taken as a starting point. It is further assumed without attempt at physical interpretation that the velocity of propagation of waves in a metal is $m(\cos\chi + \sqrt{-1}\sin\chi)$. The real value of the method may perhaps be best shown by trying to interpret this apparently unmeaning assumption. Passing over the difficulties in Fresnel's method of interpreting $\sqrt{-1}$ as extended by MacCullagh, we have on the assumption of the paper—

$$\zeta = A\sin n\{x - tm(\cos\chi + \sqrt{-1}\sin\chi)\}$$

or which is equivalent—

$$\zeta = A\sin n\{x(\cos\chi - \sqrt{-1}\sin\chi) - mt\}$$
$$= A\{\cos\sqrt{-1}\,n\sin\chi x + \sqrt{-1}\sin\sqrt{-1}\,n\sin\chi x\}$$
$$\times \sin n\{x\cos\chi - mt\}$$
$$= Ae^{-n\sin\chi x}\sin n\{x\cos\chi - mt\}.$$

The physical meaning of this equation is obvious, it clearly means absorption in the metallic medium. MacCullagh's theory of metallic reflection would bear the same relation to a theory resting upon the fact of absorption in the metal that Fresnel's theory of total internal reflection does to Green's.

In the seventh paper, "On the Laws of the Double Refraction of Quartz," we find the same method of treatment. Without any reason of a mechanical nature two equations of motion are assumed, viz.:—

$$\frac{d^2\zeta}{dt^2} = A\frac{d^2\zeta}{dz^2} + C\frac{d^3\eta}{dz^3}$$
$$\frac{d^2\eta}{dt^2} = B\frac{d^2\eta}{dz^2} - C\frac{d^3\zeta}{dz^3}$$

and the integrals of these are shown to express experimental facts. Subsequently Maxwell has obtained for magnetic rotatory polarisation the equations—

$$\frac{d^2\zeta}{dt^2} = A\frac{d^2\zeta}{dz^2} + C\frac{d^3\eta}{dz^2dt}$$
$$\frac{d^2\eta}{dt^2} = A\frac{d^2\eta}{dz^2} - C\frac{d^3\zeta}{dz^2dt}$$

It is interesting to remark that each system is strictly appropriate to the case to which it is applied. MacCullagh's equations do not apply to magnetic rotation of the plane of polarisation, for there the direction of rotation is reversed if the ray be reversed. On the other hand Maxwell's equations are not to be applied to a solution of sugar or to quartz. The distinction has been overlooked by Verdet, who treats both sets of equations as appropriate empirical formulæ for magnetic rotation; it is perhaps not surprising that Maxwell's fitted those facts the best.

MacCullagh's fame as a physical optician rests mainly upon the well-known paper entitled "An Essay towards a Dynamical Theory of Crystalline Reflexion and Refraction." This is the fourteenth paper of the series. Its position, in relation to the theories of Green and Cauchy, has been very ably examined by Prof. Stokes (British Association Report, 1862). But the appearance of Maxwell's theory of the transmission of light leaves room for a reconsideration of Stokes's criticism. The real point of MacCullagh's position may be shortly stated. In order to obtain his differential equations he must ascertain the form of the function V which expresses the work done in causing a given deformation of the medium which transmits radiation. His reasoning is obscure, but it virtually amounts to this. Let $\xi\eta\zeta$ be the displacement at the point xyz of the medium, and suppose a plane

wave propagated through it. If under these *particular* circumstances the quantities—

$$\frac{d\zeta}{dy} - \frac{d\eta}{dz}, \quad \frac{d\xi}{dz} - \frac{d\zeta}{dx}, \quad \frac{d\eta}{dx} - \frac{d\xi}{dy},$$

are given at each point, these three quantities are in general sufficient to define the direction of the normal to the wave front and the direction of disturbance. Hence—and here is the fallacy—the *general* expression for V must be a function of these three quantities. MacCullagh was probably unaware that these three quantities simply defined the angles through which the element about the point xyz was rotated by the displacement. That his expression for the function V not only rests on wrong reasoning but is actually wrong, for the case in question, where V is supposed to depend upon *the change of form* of the elementary parallelepiped, is easily seen. Suppose the deformation to be irrotational: through a given space on MacCullagh's theory V vanishes: but we know it may be anything we please. Again, suppose the medium within a given space to be simply turned through a given angle without change of shape: MacCullagh gives a finite value to V: but we know that in this case V is zero. It is a pity that MacCullagh did not keep to the method of his papers on metallic reflection and on transmission in quartz, and simply say, without admitting that V depends on the change of form of the elementary parallelepiped, "let us assume that V is a quadratic function of $\left(\frac{d\zeta}{dy} - \frac{d\eta}{dz}\right)$, &c." His theory would then have had a certain amount of analytical similarity with Maxwell's theory of electromagnetic propagation of light, though giving not the slightest adumbration of the physical basis of that theory, the facts which it covers being almost unknown when MacCullagh wrote. MacCullagh's expression for V as a theory regarding the ether as an elastic solid is misleading, but we are certainly not compelled to be so materialistic. To the student of physical optics we should say, first read Green, then read and criticise MacCullagh and Cauchy, and finally read Maxwell, not once or twice only, but until you understand him.

OUR BOOK SHELF

On the Structure and Affinities of the Genus Monticulipora and its Sub-genera. By H. Alleyne Nicholson, M.D., D.Sc., &c., Professor of Natural History in the University of St. Andrews. Pp. 240, and vi. Plates. (Edinburgh and London: Blackwood and Sons, 1881.)

THIS is a most elaborate work, on one of the most puzzling groups of palæozoic fossils, by the accomplished and industrious Professor of Natural History at St. Andrews. He gives the general history and literature of the genus, describes the morphology, dealing carefully with the dimorphism of the corallum, treats of the development of the forms, and compares them with Heteropora amongst the Bryozoa. Then the affinities of Chætetes and Stenopora are considered, and those of the Helioporidæ also. A chapter is devoted to the sub-divisions of the genus and to the consideration of the propriety of separating from it Fistulipora, Coustellaria, and Dekayia. Finally five chapters are occupied by the consideration of as many sub-genera. Yet the author modestly says that it is not a monograph of the Monticuliporidæ! The book is particularly valuable on account of the mass of careful description it contains, and the plates and cuts are excellent, and everybody who has tried to make out these tubular fossils will be grateful to Prof. Nicholson for his work. Like most palæontologists, he has suffered from the fact that his predecessors have described genera and species from very imperfect specimens. This is the curse of modern palæontology, and a clean sweep should be made of every classification which is not clear and definite, and which was founded on bad specimens. The difficulty of the subject taken up by the author may be appreciated by noticing the synonymy of the species; and it is interesting to notice how recent investigations by Busk, Waters, and Moseley are influencing the palæontology of very remote ages.

The author states that in *Monticulipora* there are no septa, and the walls are imperforate, whilst in *Heteropora* the walls are traversed by a very remarkable and exceptionally developed canal system; hence he separates the groups, but states—"In the face of the above distinctions I feel compelled to believe, in the meanwhile, that there is no real relationship at all between *Heteropora* and *Monticulipora*." "On the other hand there are strong resemblances between *Monticulipora* and its allies and various undoubted corals—principally perhaps the *Helioporidæ*." "I am at present disposed to regard the *Monticuliporidæ* as ancient groups of the *Alcyonaria*."

P. M. D.

The Evolutionist at Large. By Grant Allen. (London: Chatto and Windus, 1881.)

WIDER and wider grows the field over which newspapers and magazines exert their distributive influence. Verily, they sow beside all waters, and great is the variety of the seed. Their readers find a royal road to learning the contents of books which they are too hurried to read in full, in short essays which collect the essence, omit the difficulties, and state the conclusions of the writers in the clearest and most unqualified terms. It is satisfactory to find that an effort is made to supply modern science to such readers from competent pens.

Mr. Grant Allen has collected into this engaging little volume a series of well-judged attempts to perform this which have appeared in the *St. James's Gazette*, and no reader who would consult that class of publication for scientific ideas could help being interested and, we should hope, led on to further inquiries by it. Mr. Allen describes himself fairly when he says (p. 109), "I am not a butterfly-hunter myself. I have not the heart to drive pins through the pretty creatures' downy bodies, or to stifle them with reeking chemicals; though I recognise the necessity for a hardened class who will perform that useful office on behalf of science and society, just as I recognise the necessity for slaughtermen and knackers. But I prefer, personally, to lie on the ground at my ease and learn as much about the insect nature as I can discover from simple inspection of the living subject as it flits airily from bunch to bunch of bright-coloured flowers." And any one who sympathises with such feelings will delight in the company of "The Evolutionist at Large."

Nearly all the fresh lights which have been thrown upon the relations of the natural world by the teachings of Darwin and Herbert Spencer are here condensed and exhibited in the most simple gossipping style; while it is hardly necessary to say that the most puzzling questions that remain unanswered will suggest themselves on many a page of such an author's book. His disquisitions on the extent of animal feeling (p. 50), upon the origin of two eyes and the cross-connection of them and other organs with the brain (p. 102), are very interesting. But the most striking question which time after time turns up, as we might expect in such a book by Mr. Grant Allen, is the origin of our æsthetic sense: and since the sense of beauty is little else than a feeling of harmony with and admiration for the forms, colours, and adornments of flowers and animals; and as these are all the result of their selection by animals in choosing their haunts and their mates, we are landed at the rather humiliating con-

clusion that a sense of the beautiful and an admiration for the forms and colours of nature is only a strongly developed instinct inherited from the lower animals! An uneasy feeling is raised not only that the rebuke administered to "man, the most conceited creature," by the flea in Gay's fable is well deserved, but that the description there given of the views taken by other members of creation are far more probable and even reasonable than ever their author thought.

It would very much help the less scientific public to accept the doctrine of development if by it any imaginable explanation of the part an insect takes in its own metamorphosis, or its feelings of personal identity through the states of grub, chrysalis, and butterfly, could be suggested; but an attempt explaining so little as chapter xv. must only make the incredulous close the book more sceptical still. W. O.

An Elementary Course of Practical Physics. By A. M. Worthington, M.A., F.R.A.S., Assistant Master at Clifton College. 51 pp. (London: Rivingtons, 1881.)

THIS extremely useful and carefully prepared little book is intended to form the basis of the practical teaching of physics for schoolboys. It describes the way of performing fifty-eight experiments in elementary physical measurements. It appears therefore to have exactly struck the right line between the Scylla and the Charybdis of practical physics, in which a middle course between "merely qualitative work only leading to play" and "measurements by costly instruments requiring on an average two hours for each experiment," appears to be difficult to steer. Mr. Worthington, whose experience in teaching of this kind is considerable, has embodied the results of his labours in the present compendious little volume, and were the course he has sketched out adopted in all our public schools the gain to physical science would be great. There can be no doubt that one great drawback to the progress of students in physical laboratories even at the Universities is the want of acquaintance with the common instruments and with the principles of exact measurement. Mr. Worthington's course cannot fail to give this, and to teach moreover something of manipulation, exact observation, and of use of algebra and geometry as applied to real quantities. The acquiring of intelligent and orderly methods of recording observations is facilitated wherever possible by providing a blank schedule or form wherein to enter the various observations and their several corrections, and for comparison between the observed and computed results. The course comprises experiments in elementary mechanical measurements, centre of gravity, specific gravity, elasticity of cords, law of pendulum, &c., and also includes experiments upon the law of Boyle and upon the laws of expansion by heat and of specific heat. We trust it will not be long before Mr. Worthington adds a course of practical experiments in other branches of physics to the present series. He deserves the thanks of all who have to teach physics in the laboratory to beginners in manipulation.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

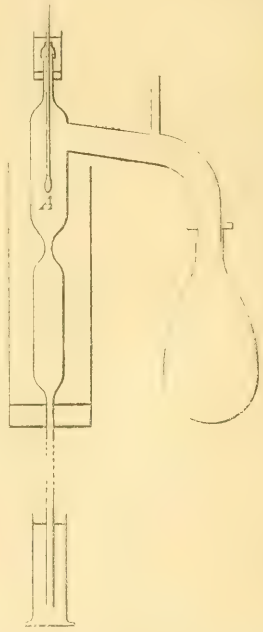
[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Hot Ice

As my name has been mentioned in NATURE in connection with Dr. Carnelley's experiments on hot ice it may possibly be convenient if I describe the experiments in which I have failed to raise the temperature of ice and camphor above their fusing-points when they are heated *in vacuo*.

On December 16, I was present at the meeting of the Chemical Society, when Dr. Carnelley showed his experiments with ice, camphor, and mercuric chloride. At the time they did not appear conclusive to me, for it seemed (although in this I am possibly mistaken) that the thermometer bulbs were too close to the sides of the containing tubes, and that they consequently did not indicate the temperatures of the solids.

A few days afterwards I tried an experiment with camphor in an apparatus so arranged that the thermometer was held rigidly in the axis of a glass tube with the bulb in the middle of a block of camphor which had been previously melted in the tube. The apparatus was exhausted by a water air-pump, and the tube containing the camphor heated. No fusion took place, and the camphor volatilised rapidly; but the thermometer did not indicate a temperature as high as 157° C. The exact temperature could not be ascertained, for a part of the thermometer stem was hidden by the caoutchouc which connected it to the tube. The



fusing point of the camphor being 176°, it is certain that the temperature was far below this, although the glass tube was softened and there were indications of decomposition of the camphor vapour by contact with the hot glass.

Air was afterwards admitted, the camphor fused down, and the air exhausted until the liquid just solidified. Heat was then rapidly applied, but the temperature remained between 170°·2 and 172° until a portion of the thermometer bulb was exposed, when the temperature began to rise. Dr. Carnelley has since informed me that he has obtained precisely similar results with camphor.

On December 30 an experiment was tried with ice in an apparatus bearing a remarkable resemblance to one recently described by Prof. Lothar Meyer (*Ber. Deut. Chem. Ges.* xiv. 718, April 11). The tube A is surmounted by a narrower tube, in which the thermometer stem was fixed by a piece of caoutchouc tube, the joint being surrounded by a tube containing mercury. To the side of A a tube about half an inch in diameter, connected with a copper flask of half a litre capacity, is joined, a branch from this wide tube leading to a Sprengel pump. The

tube A is narrowed in the middle, and its lower extremity terminates in a narrow tube about 33 inches long, and dipping into a cylinder of mercury. Some boiled water was introduced into A before the thermometer was attached, and a small quantity of water was placed in the copper flask. The air was then removed by the Sprengel, the exhaustion being facilitated by heating the copper flask. The water in the glass tube was also heated, in order to expel the dissolved air. When the exhaustion had been completed, the cylinder of mercury was raised until the mercury in the tube stood at the narrow part of A, and the cylinder surrounding the tube was filled with a freezing mixture of ice and salt, the copper flask being also placed in a similar mixture. When the water in the glass tube was solidified, the freezing mixture was removed from the cylinder, the latter lowered, and the column of mercury was depressed by lowering the cylinder of mercury until the column stood at the bottom of A.

A small gas flame was employed to warm the part of the tube containing the ice; some of the ice at the lower part of the solid plug melted and ran down to the surface of the mercury; the upper portion of the ice could not be fused in consequence of the diminished pressure on its surface. When the ice was completely detached from the glass tube a fresh quantity of freezing mixture was placed in the cylinder surrounding the lower part of A.

The air of the room was at 15° C., and the thermometer in the ice indicated − 8°. The tube A was now heated by a Bunsen burner, and the temperature shown by the thermometer was − 6°·5. A jet of steam from a test-tube with cork and narrow tube was directed against the side of A until the ice became very thin on one side of the thermometer bulb; the temperature was now − 1°. The freezing mixture surrounding the copper flask was nearly exhausted; it was therefore replaced by fresh ice and salt, and the steam once more directed against the tube. The thermometer now read − 5°·2. When a small part of the thermometer bulb was free from ice the jet of steam was stopped, and a new freezing mixture placed round the flask, the thermometer indicating − 6°·7. When about one-third of the bulb was exposed the tube was heated by a Bunsen flame and the temperature rose to + 4°, and on allowing the tube to cool it fell to − 5°. Finally, when only a very narrow strip of ice remained attached to one side of the bulb, the tube was strongly heated, and the temperature rose to + 12°, but on cooling it sank to − 2°·2.

The experiment was repeated on January 6, a jacket being placed round the tube so that the heating by steam was more regular than before. On first separating the ice from the containing tube the thermometer indicated − 8°. On heating with a Bunsen it rose to − 6°. When the tube was cold the temperature was − 14°. After passing a current of steam round the tube for half an hour the temperature was − 11°. A fresh freezing mixture was now used, and the steam again turned on; after twenty minutes a small portion of the thermometer bulb became exposed, and two minutes later the temperature was − 9°. A fresh freezing mixture was put round the flask, and when the outside of the tube was cold, the thermometer showed a temperature of − 16°. Steam was again turned on for fifteen minutes, when the temperature was − 12°. When the bulb was half exposed the steam jacket was removed, and the tube heated by a Bunsen; the temperature then rose to − 1°·5. On allowing it to cool it fell again to − 12°. When about three-quarters of the bulb was free from ice the tube was again heated by the gas flame, and the temperature rose to + 29°. The ice then fell off, and although the heating was discontinued the thermometer rose rapidly to 70°.

These experiments, as far as they go, are therefore in accordance with those of Mr. Hannay and Prof. Lothar Meyer, there being no considerable rise of temperature until either the condensation of the aqueous vapour was too slow and the vacuum thus deteriorated, or the thermometer bulb was partly uncovered, and so exposed to direct radiation from the walls of the outside tube.

Two experiments were tried with mercuric chloride, but the results were not satisfactory, in consequence of the high melting point of the solid. The temperature seemed to be above the fusing point, but it was found that the mercury in the thermometer stem had separated.

HERBERT MCLEOD

Cooper's Hill, May 3

Sound of the Aurora

UNDER the above heading Mr. Ogle, in last week's NATURE (vol. xxiv. p. 5), gives an extract from the Visitors' Book at the Æggischorn Hotel describing certain electrical effects which were experienced by Mr. and Mrs. Spence Watson, Mr. Sowerby, and myself on July 10, 1863. I would add one or two facts with regard to our position and experiences. We reached the top of the Jungfrau Joch at 10.5 a.m., and were met by a violent hail-storm, which came rolling up from the northern side of the Col. We at once started to return, and had been walking for two hours down the centre of the Aletsch glacier when the electrical effects began to be felt; we reached the Mërjelen See at 3.15, so that at the time of the occurrence we had reached the lower part of the *mêr* which is farthest from surrounding mountain tops, where the glacier is widest. We were enveloped in cloud, above which there were no doubt other clouds charged with electricity, and as they approached we were gradually being charged more and more strongly by induction from the lower cloud, and when the discharges or thunder occurred we were suddenly relieved by an electric shock. A kind of *brush discharge* of gradually increasing intensity went on for some minutes, followed by a sudden shock, and this process of bringing us up to the right state of excitement, to be relieved by a sudden shock, was repeated over and over again several times.

The hissing sounds were first heard in the alpenstocks, and gradually increased in loudness up to the sudden discharge. There were clear indications that as condensers of electricity we were not all of the same capacity. We were roped together in threes: in one set of three I was in the middle, with a guide in front and Mr. Sowerby behind. Whilst the charging was going on I felt the pricking sensation at the waist on the side where the cord was knotted, showing that those who were more influenced by electrical induction were charging the others through the rope which acted as a conductor. Judging by his actions, our guide (a young and active man) was strongly influenced by the charge, whilst Mr. Sowerby, the most staid and venerable of the party, was certainly influenced the least. In the other set of three the elderly J. M. Claret of Chamouni was least affected, whereas Mr. Watson, who was not the youngest of the party, was the most powerfully affected. These facts point to a direct relation between the temperament of the individual and his capacity for being excited electrically or his inductive capacity.

I should add that Mr. Packe has had similar experiences, but apparently to a less extent, in his walks in the Pyrenees.

W. GRYLLS ADAMS

Wheatstone Laboratory, King's College, May 9

Palæolithic Man

IN my communication to NATURE, vol. xxiii. p. 604, I chiefly restricted my notes to the higher gravels on the north side of the Thames in and near London. With your permission I will now briefly refer to some of the implementiferous gravels south of London, especially in Kent.

The best known of these are to be seen between the Reculvers and Herne Bay, where a thin stratum of implementiferous gravel caps the cliffs. Similar but deeper gravels, also bearing implements, occurs elsewhere inland, as at and near Chislet. At Canterbury a great number of implements have been found, and to these gravels and implements I would now direct attention. As a rule the Reculver instruments are sharp, unstained, and unabraded (such as have been rolled in the sea of course excepted); the Canterbury examples where the gravel is deep are found at various depths, from 9 feet to 20 feet.

Now there are two distinct classes of implements found in the Canterbury pits, the levels being, according to Dr. Evans, about 80 feet or 100 feet above the river: in one class the specimens are well made and almost as sharp and unstained as when first turned from the maker's hands, in the other the implements are much more rudely made, deeply stained all over of a dark ochreous brown colour, and abraded in a high degree. These latter implements come from distinct strata or deposits of ochreous brown rolled stones that appear to have been brought from a long distance. In my own collection of twenty-nine examples from Canterbury one half are sharp and bright, the other half greatly rolled and deep brown in colour. To my mind these two classes of instruments represent two totally distinct periods in the Palæolithic age immensely removed in time from each other, the abraded examples being the oldest. A point of importance to be observed in the deeply ochreous implements is that many of them were slightly splintered or broken when they were deposited in the Canterbury drift; now these broken and

splintered parts are bright, lustrous, and non-ochreous, exactly resembling in the fractured parts the bright and unabraded implements. This fact appears to me to demonstrate that the abraded ochreous implements acquired their ochreous crust elsewhere, and were objects of great antiquity when the Canterbury gravels were laid down. I have one of these deep-brown greatly-rolled flint implements that was found amongst chert in the famous pit at Broom, near Exeter: the deep ochreous colour was not derived from chert gravel. From whence have these generally massive, abraded, ochreous implements been derived, and how laid down in distinct deposits?

As an instance of very high implementiferous gravels, the same distance south of London as the Ware gravels are north, the ancient gravels on the escarpment of the hills north of Sevenoaks and Ightham may be cited. Some of these heights exceed by 200 feet the heights of the Hertford and Ware positions.

Dr. John Evans, in his admirable book on the "Ancient Stone Implements of Great Britain," pp. 531-532, records the important discovery (on the surface) of ochreous and abraded implements at great heights near Currie Wood, a few miles south of St. Mary's Cray, Kent, at 300 feet above the valley of the Darent, and 500 feet above the sea. Dr. Evans also says (p. 531), "It is, however, necessary that further discoveries should be made in this district before it will be safe to speculate on the origin of these gravels and their relation to the superficial configuration of the neighbourhood." My friend, Mr. Benjamin Harrison of Ightham, has during the last year instituted a rigorous search over the high level gravels south of this district. A tributary of the Medway rises at Ightham, near Sevenoaks; the level of the present stream near the village is 254 feet, and an outlying bed of old river-gravel is found at 330 feet, and another bed up the stream at an altitude of from 380 feet to 400 feet. In these high-level Wealden gravels Mr. Harrison has recently found palæolithic implements *in great numbers*, generally massive, ochreous, and abraded. At 312 feet he has found them *in situ*, and on the surface as high as 335 feet. More recently Mr. Benjamin Harrison has examined the old river gravel at Dunk's Green (two miles and a half south of Ightham), and here at a level of 200 feet has proved the beds to be implementiferous. For these facts and heights I am indebted to Mr. Harrison, who has given me his permission for their publication.

In these two letters I have chiefly confined myself to statements of dry facts, purposely abstaining from any comments on the meaning of the heights, &c., referred to.

Naval Cadet Examinations

I WISH to bring to your notice the injudicious severity to which our competitive examinations have of late attained, regardless, as it appears to me, of the possible injury they may inflict on the health of those who are forced to strain every power, both physical and mental, in the struggle.

The most recent example of the kind is, I believe, the New Standard for Naval Cadetships, which requires boys from between the ages of twelve and thirteen and a half to pass a competitive examination in Latin, French (both translating and speaking), arithmetic up to decimal fractions, algebra, including fractions and simple equations with one unknown quantity, geometry up to first twenty-six propositions of Euclid, English—with Scripture history. They are further tempted, if ambitious, to take algebra up to quadratic equations, and geometry up to the end of the first book of Euclid.

Now when the object to be obtained is no less than a career for life, one can imagine what a force of pressure—from the parent anxious to provide for his son, from the schoolmaster's pride in his pupil, and from the boy's own ambition—is brought to bear to urge nature to the utmost in the trial.

The casualties—for we are entitled to use the expression—that have already occurred under the system have been sufficiently numerous to make any one who will pause to think seriously anxious.

Education is most valuable, but when its attainment is at any time carried out at the expense of health to the pupil it is a failure. "Mens sana in corpore sano" is above everything to be prized, and he who enters upon life's work possessed of that advantage is fittest for its trials.

I will quote an extract from the *Lancet*, which treats the subject from a professional point of view and with an admirable clearness. It says:—

"There can be no room to question the extreme peril of 'over-work' to growing children and youths with *undeveloped* brains. The excessive use of an immature organ arrests its development by diverting the energy which should be appropriated to its growth, and consuming it in work. What happens to horses which are allowed to run races too early happens to boys and girls who are over-worked at school. The competitive system as applied to youths has produced a most ruinous effect on the mental constitution which this generation has to hand down to the next, and particularly the next-but-one ensuing. School-work should be purely and exclusively directed to development. "Cramming" the young for examination purposes is like compelling an infant in arms to sit up before the muscles of its back are strong enough to support it in the upright position, or to sustain the weight of its body on its legs by standing while as yet the limbs are unable to bear the burden imposed on them. A crooked spine or weak or contorted legs is the inevitable penalty of such folly. Another blunder is committed when one of the organs of the body—to wit, the brain—is worked at the expense of other parts of the organism, in face of the fact that the measure of general health is proportioned to the integrity of development and the functional activity of the body as a whole in the harmony of its component systems. No one organ can be developed at the expense of the rest without a corresponding weakening of the whole. These faults of 'training' attain their supreme height of folly and short-sightedness when they are committed in reference to the youths destined for the public services. They are especially illustrated by the 'Regulations respecting Naval Cadets' just issued, and which will take effect in June of the present year. The work of the Civil Service Commissioners in respect to these classes of the possible servants of the State is personally and racially *destructive*. Sooner or later public opinion must recognise this fact, and then perhaps the Government or the Legislature may be moved to interpose—not before, but when it is too late."

We live in an age of reactions, when ideas are hastily adopted, hurriedly brought into practice, and fanatically adhered to. I can only hope that public opinion will recognise the danger that the *Lancet* so clearly points out, and that the Government may interpose before it be "too late." J. D.

Flame-Length of Coal-Gas

I HAVE recently measured the flame-length of a sample of coal-gas burning in air and burning in nitrous oxide (N_2O). The flame-length in air was $\frac{1}{10}$ths of an inch and $\frac{5}{7}$ths in nitrous oxide. The relation of 5 to 13 is very close to what my theory would suggest, and is a confirmation of my law published in your issue of April 7.

I might add that I have recently noticed the flame of a mixture of hydrogen and nitrous oxide burning in air to develop a bright white spot about one-third from the top of the flame, and when the proportion of nitrous oxide is larger, to extend into a cone reaching to the jet. I have not examined this flame with a spectroscope, but am certain, from the whiteness of the flame, that the spectrum would be continuous. LEWIS T. WRIGHT

Water in Australia

A GENTLEMAN recently returned from Australia believes that the arid plain which occupies the centre of that island-continent might be amply supplied with water and converted into rich farm land by a very simple process. He founds his belief upon observed facts in the three sciences of botany, physiography, and geology, thus:—

1. Gum-trees and the mallee scrub flourish there. The gum-trees grow to a great size and withstand the drought of many summers. They must have water; whence do they obtain it?

2. Rivers which flow towards the centre from the mountain ranges along the coasts have no apparent outlet into the sea, but are lost in the desert. What becomes of them?

3. The underlying rock of the central plain is an almost horizontal bed of Tertiary Sandstone.

The conclusion is that the Sandstone is saturated with water and forms an immense reservoir from which existing trees draw their supplies by deep tap-roots, and that by sinking wells in the desert this water could easily be reached.

The author of this theory, wishing only to confer a public benefit, desires to bring it under the notice of scientific men,

that it may be either turned to account or shown to be erroneous. If there is even a remote possibility of its truth it would seem worth while for one or more of the Colonial Governments to have borings made in order to test it. F. T. MOTT

Birstal Hill, Leicester, May 5

The Glacial Blocks of Zinal

MAY I through your columns express a hope that other qualified observers will volunteer to take charge of work such as I propose to do this summer as my share?

This is to mark the position of large blocks of stone on the glacier of Zinal. You will, I hope, receive the report of my friend, Prof. F. A. Forel, upon periodical variations of glaciers. Therein are sketched some of the existing data. I have for years much wished to organise a simultaneous action. With a Galton's pocket altazimuth, a pot of paint, and the superb map on the scale of $\frac{1}{10000}$ of the Swiss Alpine Club (Sheet III. of the Valais du Sud), it will be a pleasant and not a difficult task to lay down a few good triangles, and to paint a letter and indication of bearings of stones along and athwart the great glacier, with which I am well acquainted. The Swiss Alpine Club has erected a hut at Les Mountets, which, at about 9500 feet above sea-level, will form a capital base of operations. The pre-eminently grand scenery would itself reward the short sojourn necessary for our purpose. To secure uniformity of action and registration I propose that we should place ourselves in communication with M. F. A. Forel. I shall be very glad to hear from gentlemen—at this address up to the end of June, and then at the Hôtel d'Anniviers, Vissoie sur Sierre, Canton Valais, the most comfortable quarters in the Val d'Anniviers, about 4000 feet above sea-level, three hours' and a half drive from Sierre railway station.

I would suggest, as good head-quarters and interesting fields of observation: (1) the hotel at the Riffelberg, with the Gorner and Findelen glaciers; (2) the hotel at Saas in Grund, with the Fée and other large glaciers in the Saas-Thal; (3) the hotel at the Maltmark See, with the Allalin and Schwartzberg glaciers; and (4) Macagnaga as a southern station. I myself, also, ask for personal assistance. MARSHALL HALL

Villa Chessex, Veytaux-Chillon, Canton Vaud, Switzerland, May 3

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE AT ALGIERS[1]

III.

THE main result of the Algiers Congress has undoubtedly been the acquisition of a considerable amount of matter tending to the development of the great French colony, while at the same time it has been the means of making hundreds of Frenchmen well acquainted with the principal features—physical, geographical, and political—of a country which they knew previously only by name. The general results, as far as universal science is concerned, have been slight, but we cannot regard the Congress as less than a success. It is as if the French had said to the world of science, "Come and see this undeveloped country, and help us to apply each and all of the sciences to its special requirements, to aid us in a more perfect colonisation." The work has been nobly initiated by the French. It is probable that not less than a hundred millions sterling have been expended in the country. The roads and bridges, and telegraph and postal systems are perfect. Everywhere you find evidences of complete organisation. Every small village has its mayor and council; its post-office and diligence service; its water supply and sanitary arrangements; its groves of eucalyptus-trees and trimly-planted streets. Let us take one example—that of Bordj-Menaïel, a village to the east of Algiers, which we visited in the course of an excursion. Twenty-three years ago Bordj-Menaïel was made a centre of colonisation, and 1718 hectares of land were distributed among the first colonists. The total superficies of the commune is 4200 hectares, and it contains a population of 837, of whom 659 are Europeans and 178 indigenous races. Situated at a distance of 70 kilometres from Algiers and 38 from Dellys, it is traversed by the main departmental road passing to Eastern Algeria. It stands in the midst of a highly fertile alluvial plain, 28 metres above the sea, and is watered by the Isser. This commune possesses the following municipal officers: mayor, deputy-mayor, justice of the peace, sheriff's officer, receiver of "contributions diverses," a recorder of the census, a manager of ponts et chaussées, a departmental business agent, a bureau of posts and telegraphs, a "médécin de colonisation," a midwife, and a pharmacien. Its spiritual and intellectual wants are provided for by a *curé* and two schools. Since 1873 a brigade of gendarmerie has been stationed in the village. The organisation appears excessively elaborated for so small a population; but we must remember how doubly necessary such arrangements become in a new colony, which without sufficient proofs of the strong arm of the law would speedily become lawless, and without the benefit of well-directed and properly enforced municipal arrangements would form an ill-regulated and degenerating community. The bureaucracy evidently enters largely into the French system of colonisation.

At the present moment a project is before the Chamber for the completion of the colonisation of Algeria by the creation of 300 new villages, which, like Bordj-Menaïel and the existing villages, are to be built and thoroughly organised before colonists are invited to accept the grant of land in the commune and take up their abode in the village. Such of the existing villages as we saw were of one and the same type: the church and water-supply in a central square, from which two or more streets proceeded; the mairie, a few shops, one or more inns, and a post-office. In some villages—Palestro, for example, many of the inhabitants of which were massacred by the Kabyles so recently as 1871—there was a large space, surrounded by a high wall furnished with loopholes, in which the inhabitants could take refuge in the event of a sudden descent of the natives. Many of the colonists are Alsatians or Lorrainers who emigrated at the close of the Franco-Prussian war. They all appeared happy and contented, and their farms and gardens were flourishing. Their worst enemies are drought and fever; the former is being provided against by new systems of irrigation, and the latter by the planting of thousands of eucalyptus-trees. At Blidah we found a perfect example of the most developed system of irrigation. A ready supply of water is obtained during many months of the year from the mountains, and this is led by small brick-lined watercourses through the gardens. A main watercourse passes a line of houses, the garden walls of which are furnished with small trap-doors by which at any time a portion of the stream can be diverted into the garden. Of course rain is always looked for with great anxiety, specially between the months of May and September, when the grain crops are wholly dependent upon it. In the south of Algeria there exist at this moment places where no rain has fallen for *six years*, and of course any attempt at cultivation is here impossible.

Towards the end of the Congress several of the sections showed greater vitality than at the commencement. In the section of Mathematics there was for the first time a fair show of papers, for the most part devoted to pure geometry. The foreign mathematicians—Leguine of Odessa, Oltramare of Geneva, and Fiedler of Zürich—contributed their quota. M. Trépied brought forward a project for the construction of an observatory at Algiers. M. Picquet has been elected president of this section for next year. In the section devoted to Civil Engineering the most important papers were by Col. Fourchault on defensive villages, and by M. Trémaux on irrigation. M. Gobin is president for next year. In the Physical section papers were read by M. Gaussen on photometric photography, and by Prof. Tacchini on the solar protuberances.

[1] Continued from vol. xxiii. p. 607.

There was no paper of special interest in the Chemical section, of which M. Grimaux is president for 1882. The section of Meteorology was very active at the last, and supplied some interesting papers on the meteorology of Asia, of the Sahara, and of the district between the Atlas and the Cevennes; also on meteorological instruments—thermographs and anemographs, and registering barometers. MM. Denza and Tacchini among the foreigners contributed largely to this section. M. Fines is the president for 1882. The Geological section had no communications of general or special interest. Professors von Szabo of Buda-Pesth and Villanova of Madrid both contributed papers, and an interesting communication was made by M. Fusch (who is president of the section next year), on the lead and iron mines of Tunis, and the copper mines of the Petite Kabylie, a district to the east of Algiers. The Botanical section announced only two papers of very limited interest for the last day but one of the Congress, and it did not meet at all on the last day. M. Ed. Bureau is president for 1882. The sections of Zoology and Zootechny also showed signs of languishing. On the other hand the section of Anthropology exhibited the greatest vigour from first to last, and on the last day of the Congress no less than sixteen papers, many of them of great local interest, were announced. Among these we may specially mention observations on the Kabyles of the Djurdjura, and on the Tziganes; on the Romans in Africa, and the Berber migration; on the civil, political, and religious institutions of the Jews; and on craniometrical studies in the oasis of Biskra. A prehistoric map of the north of Africa was discussed by M. Cartailhac. Anthropology is one of the sciences which has benefited most by the Algerian Congress. M. Henri Martin is president for 1882.

The interest in the Medical section continued to the last. We have before had occasion to remark that the Congress to a great extent was a medical *réunion*, and more than one-fourth of the members were medical men. Seventeen papers were announced for the last day of the session, and fourteen had been read the day before. The most interesting to the general non-medical members were on the epidemics of Algiers, on acclimatisation, and on the climate of Algiers as regards its influence on consumptive patients. Dr. Azam of Bordeaux is the president for 1882. The success of this section has been complete; a large number of very valuable papers have been communicated, and the attendance has always been large. The final papers communicated to the section of Agronomy related mainly to the development of the agriculture of Algiers: on the cultivation of cereals and of sorghum; on the rearing of cattle; on agricultural railways; and on watercourses. M. Dubort is president for 1882. The section of Geography was also mainly devoted to Algerian questions: the Trans-Saharian Railway; the geodesy and topography of North Africa; maps and geographical vocabulary. The section of Political Economy devoted its last hours to the dominant subject throughout—the colonisation of Algeria, the treatment of the indigenous races, and the peopling of the Sahara. Finally the section of Pedagogy visited the principal schools of the city, and collected as much information as possible concerning the methods of instruction.

At the commencement of the Congress the members were presented with a volume entitled "Notices Scientifiques, Historiques, et Économiques sur Alger et l'Algérie." The second volume is to be ready before the end of this month. The work is compiled by twenty-one residents in Algeria, each one very competent to discuss the subject of his contribution. Thus the geography is described by the president of the Algerian Geographical Society, the general administration by the secretary of the Council of Government, and the history by the Director of the École supérieure des Lettres. The whole constitutes the most complete and exhaustive history of Algeria which exists. Starting with the geography, hydrography, and climatology of the country, an able discussion of its complex meteorology follows. Statistics are given of the barometric pressure, mean temperature, hygrometry, winds and atmospheric currents, electricity, rain, evaporation, &c. There are forty meteorological stations in the country, extending from Mogador in Marocco, to Sfax in Tunis. A daily bulletin has been issued since 1875, and it is distributed over thirteen points on the coast. The very interesting geology and mineralogy of the country forms an article by M. Pomel, from which we learn that copper, argentiferous lead, zinc, iron, building-stones, and salt are profitably mined. About 3500 miners are employed, more than half of them finding occupation in the province of Constantine. The succeeding articles treat of botany, zoology, and anthropology. The major part of the indigenous population consists of two ethnic groups: on the one hand the Arabs, nomad tribes, shepherds, with a patriarchal organisation, and with warlike and religious feudality (*féodalité guerrière et féodalité religieuse*); on the other the Kabyles, cultivators of the soil, non-nomadic, and with a social organisation which is democratic and communalistic.

An article of much interest, by Dr. Liautaud, treats of the colonisation and peopling of Algeria. We have no space to give even an outline of its contents, but we commend it to every one interested in the present and future of the colony. It is followed by articles on the actual state of agriculture; industry and commerce, public works, the financial system, and the Algerian budgets. Then a general survey of the history of Northern Africa is given by M. Masqueray; archæology by M. MacCarthy; the general administration by M. Dimier; judicial organisation by M. Fau, Advocate-General of Algiers, and taxes and imposts by M. D'Aufresne.

We will glance for a moment at some of the statistics connected with public works and education. When the French took possession of Algiers in 1838 they found a *tabula rasa* as regards public works. In 1843 they set on foot the drainage of the Mitidja; between 1840 and 1846 ports were constructed, and lighthouses placed along the coast, and great systems of excellent roads were inaugurated; in 1857 railways were commenced. Forty-five lighthouses are now in operation, and there are seven ports. In 1830 the imports amounted to a value of 5,000,000 francs, and the exports to 1,500,000 francs; while in 1879 the values were respectively 272,126,102 francs and 151,918,421 francs. There are 10,506 kilometres of roads and 1282 kilometres of railways. There are now about 600 agricultural villages dispersed through the three provinces of Algiers, Oran, and Constantine.

As regards public instruction, higher instruction is given in four schools, which no doubt will soon be united into a university: law, medicine, letters, and science. Secondary education is provided by a Lycée in Algiers, ten communal schools, and three free schools. The former contain 3405 pupils, among whom there are 365 Jews, and 272 Mussulmans. The number of primary schools, including Arabic, Kabylic, and Arab-French schools is 703, in which are educated no less than 53,803 pupils—28,803 boys, and 24,501 girls. The boys consist of 11,639 French, 7336 foreigners, 7408 Jews, and 2420 Mussulmans.

On April 20 the various excursions commenced: eastward to the confines of Tunis, southward to the Sahara, and westward to the boundaries of Marocco. We have not space to tell how we went into the country of the *indigenes*—the Kabyles who were driven into the mountains when the Arabs first took possession of the land—how they met us headed by their chiefs, and conducted us, with accompaniments of barbaric music, and discharges of guns to awaken the echoes, through the magnificent gorges of Palestro; and how on the following morning

we breakfasted with them in one of the most picturesque spots imaginable, and finally how we realised with difficulty that we were only four days' journey from London, while breakfasting, under a bower of carouba branches, off sheep roasted whole over hot ashes placed in holes in the earth, manipulated with hunting-knives and without forks, flat circular cakes of Kabyle bread serving us for plates, and gigantic wooden bowls of *kous-kous* as a second course.

The amicable attitude of these once savage aborigines seemed to us to re-echo the key-note of the Algiers meeting of the French Association; to proclaim loudly and with no uncertain sound that the "conquête pacifique de l'Afrique septentrionale par les Français" has indeed become an accomplished fact. G. F. RODWELL

ELECTRIC LIGHTING[1]

II.

THE second district of the City which has been illuminated by electricity is that embracing Blackfriars Bridge, upon which there are seven lamps; Bridge Street, in which there are four lamps, Ludgate Circus taking three lamps; Ludgate Hill four lamps; north side of St. Paul's six lamps; and Cheapside, as far as King Street, eight lamps; thirty-two lamps in all, replacing 150 gas lamps; and moreover, all these lamps are fixed upon one circuit, which is operated practically by only one machine, and that fixed more than a mile away, at the manufactory of the Brush Company in York Road, Lambeth. The total length of this circuit is over 20,000 feet. It consists of a copper cable made up of seven best copper wires surrounded with a thick layer of gutta-percha protected externally with tape that has been well tarred. This wire gives a total resistance of 7·5 ohms., and is protected by iron pipes like the Siemens method, and laid on the principle so well known in telegraphy. The dynamo-machine is of the familiar Brush form, and at present there are two machines of the size known as No. 7 cabled up in series, but forming practically only one machine. These two machines are intended to be replaced by one dynamo-machine, which, at a velocity of 800 revolutions, and worked by 32 indicated horse-power, will maintain forty lamps burning. The main feature of the Brush system is its simplicity, one machine working a number of lights, and those who visit the engine-room of Messrs. Siemens, and then that of the Brush Company, cannot help being struck by the immense difference in the contrast between the two. In Siemens' engine-room one feels in the midst of a whirling cotton manufactory; at the Brush works one sees nothing but a single engine working a single machine quietly and without fuss or flurry.

At present a Galloway engine is used by the Brush Company, but when the large 40-light dynamo-machine is set to work a Brotherhood 3-cylinder engine of 32-horse power will be used. These engines are admirably adapted for electric light purposes; they are bolted on to the same frame as the dynamo-machine, and give a compactness and solidity to the whole that is very striking.

The Brush lamps differ but very little from the generality of arc lamps. The carbons are maintained apart by what is known as a "sucking" coil; and the lamp possesses one or two very ingenious designs to shunt it out of circuit when anything fails and to shunt it in when all is in order. It is a kind of duplex lamp, supplied with a double set of carbons, each of which burns for eight hours, the total illuminating durability of the lamp being therefore sixteen hours. These lamps are fixed upon the ordinary lamp-posts, which have been raised 2½ feet higher than usual, so as to maintain the lamp 16 feet from the ground. They are surmounted by very ugly roofs that are neither covers nor reflectors, and the mode in which these lamp-posts have been utilised is the least commendable feature of this system. Indeed the Company might have made much more of their facilities. Compared with the tall posts in the remainder of Cheapside they make an unfavourable impression. The globes that embrace the light are too small, and the Company itself seems not to have arrived at the proper decision as to the best quality of globe to use, for in some places the lamps have clear globes, in others ground-glass, and in others opal globes, made, we believe, by Mr. Frederick Siemens of Dresden.

It cannot be said that the mode of illumination adopted by the Brush Company is perfect at present. The theory of the proper distribution of the light has been neglected. The lamps are scattered about in an irregular manner that is quite offensive to the eye, and though the effect of each lamp is certainly brilliant, the effect of the whole is rather displeasing. It is very wonderful that so much light should be produced from a point so far, and there is no doubt that the public mind has been captivated by the brilliancy of the lamps. The scientific eye however sees room for improvement, and it is hoped for the sake of the success of the experiment that the Brush Company will be guided by the experience of disinterested persons. The great merit of their system is the simplicity of the machinery employed, as well as the brilliancy of the light, but occasionally the lights are subject to great want of steadiness, and it is much feared, with the quality of the cable they have used and the enormous electromotive force, that the usual faults accompanying underground wires will develop themselves rather largely. In fact, two very serious breaks-down have already occurred, and they are about to replace their conductor by a better one. They will have to pay dearly for their neglect of common experience.

So far the experiment has shown that the practical lighting of streets by electricity is not only feasible but practicable. Moonlight has certainly been thrown into the shade, for the streets of the City are better illuminated by electricity than by fair Luna. It is quite possible to read a letter or to see one's watch at any point in King William Street. Indeed the smallest object can be seen anywhere, even in the middle of the road. Running-over has been rendered impossible.

The outside districts not specially favoured are clamouring for electric lighting, but much has yet to be learnt before the experiment can be determined as final. For instance, we have the Lontin system to be tried, and we should certainly like to see that most energetic and successful engineer, Mr. Crompton, test his system in the London streets. Incandescent lamps are looking up and deserve a trial.

The best mode of distributing light has not yet been settled.

It would seem that a compromise between the centralised system of Siemens and the distributed system of the Brush Company is that needed to solve the problem of proper street illumination. But instead of carrying lamps irregularly down streets on hideous lamp-posts it would almost seem that the ancient defunct mode of swinging lamps across streets from housetops would be a better mode of illuminating streets. Take, for instance, Regent Street. If that street had suspended above it, at the height of 40 feet or 50 feet and at about every 100 yards, a Brush lamp fitted on the top of a graceful iron arch, or suspended on wire ropes between the tops of the houses, nothing could possibly be greater than the effect. Light arches thrown across the street might even be a convenient mode of suspending the wires forming the circuits, for overhead wires have a considerable advantage over underground wires in this, that they cool more rapidly and allow more electricity in consequence to pass through. More than that, they require no insulation, and the money thrown into their insulation could be thrown

[1] Continued from p. 7.

into their greater mass and greater strength. We illustrate this idea in Fig. 1. The City of London authorities who have shown so much energy and commendable zeal in carrying out this experiment would still further confer a favour on the public if they were to remove their hideous heraldric excrescence on the top of the so-called Temple Bar Memorial, and replace it by a handsome bronze pillar 30 feet or 40 feet high carrying a bright and brilliant electric light.

The Siemens system compares favourably with the Brush system in one respect, and that is they do not throw all their eggs into one basket. In their distributed system they have arranged the lamps on two circuits, so that each alternate lamp is on a different wire, and if anything goes wrong with the one circuit only alternative lamps go out, and not all. With the Brush system, on the contrary, if any fault occur in the wire in any of its length of nearly two miles, then every lamp on that circuit must go out.

The effect of fogs upon this system will be narrowly watched. It may happen, and probably will, that the fogs will be absolutely utilised by the electric light, for the reflection in the neighbourhood of the light by the small particles that constitute the fog throwing back the rays of light will help to illuminate the street, and so to a considerable extent relieve the impression now produced by dark fogs.

Of the efficiency of the system, as we have said, there can be no doubt. As to its economy, experience alone can determine. That the firms themselves require experience on this point is evident from the disparity in the charges made by the two firms competing. The Brush Company only estimate the cost of working their system at 660*l.*, which is the cost of gas: Siemens Brothers

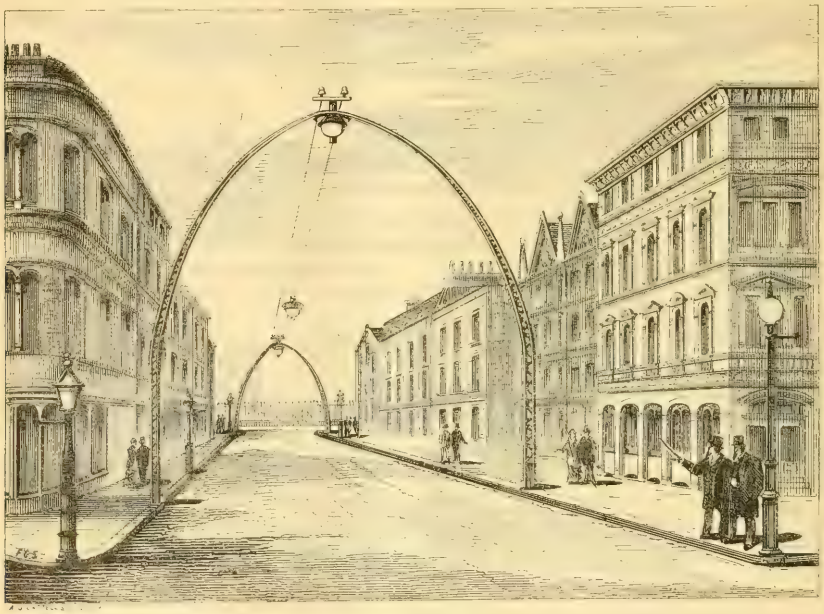

Fig. 1.

estimate the cost of working at 2270*l.*, nearly four times the cost of the Brush. We are inclined to think that a mean must be taken between these two. It is hopeless to expect that electric lighting in every case can be done at the cost of gas. Electric lighting is a luxury, and as a luxury we must expect to pay for it. Nevertheless it must not be forgotten that gas utilised as a motor can produce eleven times the quantity of light by the aid of electricity than it produces by direct combustion. This calculation is interesting. One hundred cubic feet of gas per hour can be made by combustion to produce 300 candle-power. The same quantity of gas used in a gas-engine to rotate a dynamo-machine will produce a light equal to 3750 candles, an illuminating power twelve times greater. Hence there must also be some cases in which the electric light can economically supplant gas; whether it can do so in the case of street-lighting remains to be seen by the great experiment now being tried.

There are two or three very interesting points on the line of illumination where comparisons can be made between the different systems. For instance, from the middle of Blackfriars Bridge there is a good comparative test between the Brush and Jablochkoff systems; while at the corner of King Street there is an equally excellent opportunity to examine the merits of the Siemens distributed and the Brush systems. Photometric measurements at each place prove that the Brush Company's estimate of the light power of their lamps is absurdly exaggerated; 750 candles would be a very fair figure to give the lamp. The unhesitating opinion is that comparing each individual lamp, the Brush surpasses the others. In fact there is little difference between the smaller light of Siemens and the Jablochkoff, excepting this, that the Jablochkoff, by its variation and pinkish effects, irritates the eye considerably, although in bright weather the effect on the water is sparkling and brilliant. The Jablochkoff system has been entirely put in the shade by this interesting experiment. Though however we are obliged

to express our opinion that the Brush lamp, *per se*, is the best, their system of illumination and distribution of posts cannot be compared with the care and skill evinced by the Messrs. Siemens. If either company were to try our suggestion, and illuminate down the centre of the street, maintaining the line of the street in their line of lights, we should have another interesting experiment that would go far to solve this question.

One last point deserves attention. It is the effect which these strong and powerful electric light currents have on the working of the telegraph. It was feared that their presence would deteriorate the working capacity of telegraph wires, and undoubtedly it would be so were it not that, taking advantage of the warnings given them, the electric light people have in all cases adopted a *return* wire, so as to make their circuit completely metallic throughout. We are glad to learn that this has proved quite effective except in one instance, where along London Bridge the return wire has been taken round the other side of the bridge, and here considerable disturbances have been experienced in certain telephone circuits from the contiguity of the electric light currents. No other disturbance has as yet been experienced.

We have also as yet to experience the effect of weather. Up to the present moment it has been all in favour of the electric light—bright, clear, cheerful skies have given to the light a clearness and brilliancy that have created for it a strong feeling. When thick weather and rain and fog occur there may be a change in this opinion, not only from a disturbance of the penetrating power of the light, but on the effect of rain and moisture on the wires conveying the currents.

(*To be continued.*)

DR. HOLUB'S AFRICAN TRAVELS[1]

I.

FROM his boyhood days Emil Holub determined he would explore some of the out-of-the-way portions of the African continent, and in 1872 the opportunity was presented to him of travelling in the southern parts of that great and still unexplored country. The result of seven years labour, during which period of time he made three several journeys of investigation, are now in these volumes laid before the public. In Dr. Holub's first journey he started from Port Elizabeth, crossing the Cape Colony district and the extreme south-west corner of the Orange Free State, to Kimberley. As far as Grahamstown he could have had the modern convenience of a train, but preferred a two-wheeled cart drawn by four small horses, making about eight miles an hour. The country is very charming for the greater part of this route, the road being beneath the brow of the Zuur Mountains, which with their wooded clefts and valleys, and their little lakes inclosed by sloping pastures, afforded many interesting views. The fauna was as varied as the flora, and numerous captures were made by the way. Even large game like elephants were to be met with, and the author records a sad accident which happened in the underwood by the Zondago River, between Port Elizabeth and Grahamstown. A black servant sent to look for some strayed cattle had been met by a herd of passing elephants, some of whom knocked him down and then trampled him to death. In this district these big animals are under the protection of the Government, and not being often interfered with, they would seem to have no great fear of man. The springbok (*Antelope euchore*) is noticed as still in some districts swarming, though its numbers must be rapidly diminishing, as Dr. Holub saw whole waggon-loads brought to Kimberley, where the carcases were sold at prices varying from three to seven shillings a head. Among other wonderful instances given of the great skill of the Dutch Boers in bringing down these swift creatures, he tells of one expert marksman killing by a single shot from his breech-loading rifle two of these antelopes.

Towards Colesberg the country forms a high table-land; it is on an affluent of the Orange River. On this table-land there was a herd of upwards of fifty quaggas, the only herd the author could hear of in South Africa. The farmers have lately spared them, so that during the last ten years they had increased to their present number from a small herd of fifteen. Philippolis, the first town entered of the Orange Free State, is described as dreary-looking, the houses mostly unoccupied, and the general aspect most melancholy. On the way to the Diamond Fields nothing but bad roads and worse weather were encountered; the wind was piercing, and snow actually fell. Fauresmith, one of the most considerable towns in the republic, although consisting of not more than eighty houses, covered a considerable area. It was clean and pleasant-looking, and here the author thought of settling for a time, and by the practice of his profession saving enough of money to enable him to start afresh for other fields; but the fates were against him, and he was, after a few days, obliged to push on to the Diamond Fields, and the following extract will best tell of these:—

"The first day upon which I set my eyes upon the Diamond Fields will ever be engraved on my memory. As our vehicle made its rapid descent from the heights near Scholze's Farm, and when my companion, pointing out to me the bare plains just ahead, told me that there lay my future home, my heart sank within me. A dull dense fog was all I could distinguish. A bitter wind rushing from the hills, and howling around us in the exposure of our open waggon, seemed to mock at the protection of our outside coats, and seemed resolved to make us know how ungenial the temperature of winter in South Africa could be; and the grey clouds that obscured the sky shadowed the entire landscape with an aspect of the deepest melancholy. Yes; here I was approaching the Eldorado of the thousands of all nations, attracted hither by the hope of rich reward; but the nearer I came the more my spirit failed me, and I was conscious of a sickening depression. Immediate contact with the fog that had been observed from the distant heights at once revealed its true origin and character. It proved to be dense clouds of dust first raised by the west wind from the orange-coloured sand on the plains, and then mingled with the loose particles of calciferous earth piled up in heaps amidst the huts on the diggings. So completely did it fill the atmosphere that it would require little stretch of imagination to fancy that it was a sand-storm of the Sahara. As we entered the encampment the blinding dust was so thick that we could only see a few yards before us; we were obliged to proceed very cautiously, and before we reached the office of the friend I had to call on, another mile or so farther on, our faces and our clothes were literally incrusted. We only shared the fate of all new-comers in feeling not only distressed but really ill; the very horses sneezed and snorted, and showed that the condition of things was no less painful to them than to their masters. Here and there on both sides, right and left, wherever the gloom would permit me to see, I noticed round and oblong tents and huts intended for shops, but now closed, built of corrugated iron. Under the fury of the wind the tent-poles bent, and the ropes were subjected to so great a strain that the erections threatened every moment to collapse. Many and many a sheet of the galvanised iron got loose from the roofs or sides of the huts, and creaking in melancholy discord, contributed as it were to the gloominess of

[1] "Seven Years in South Africa. Travels, Researches, and Hunting Adventures between the Diamond Fields and the Zambesi." By Dr. Emil Holub (translated by Ellen E. Frewer). With about 200 original illustrations and a map. In two volumes. (London: Sampson Low, Marston, Searle, and Rivington, 1881)

the surroundings. In many places too the pegs that had fastened the tents to the ground had yielded to the pressure, and sheets of canvas were flapping in the air like flags of distress. Truly it was a dreary scene, and I sighed at my dreary prospect."

Here Dr. Holub spent some months, making but one excursion at Christmas time (1872) just within the border of the Free State, to enjoy a little fresh air and have a shot at the baboons. In this portion of his work he gives a very interesting account of the diamond workings at Kimberley, and of the motley crew of workers that he met. Some views of the Kimberley Kopje as it appeared in 1871 are given, one of which (Fig. 1) will give our readers some idea of the dreary aspect of a "diamond quarry." His medical practice increased so rapidly that by the end of January, 1873, he was enabled to purchase a waggon and a good many of the requisites for travel, and early in February he actually started out on his first long journey of exploration, which, however, he from the first only regarded as one of reconnaissance, with the object of getting in part acclimatised to live in the open air, and to acquire by actual experience a knowledge of what would

Fig. 1.

be necessary for a prolonged journey into the interior. The first village passed through was Pniel, a German missionary station among the Koranna. With the exception perhaps of the Matabele, no native tribe appeared to have been so little influenced by missionary labour. Their culture is of the very lowest grade. Of all the South African races the Koranna bestow the least labour upon the structure and the least care upon the internal arrangements of their dwellings. Their huts (Fig. 2) consist of a bundle of branches about six feet in length, the upper ends tied together, the lower arranged in a circle, some rush-mats thrown over this hasty framework, in which an aperture is left large enough to admit a human being on all fours. A hollow dug out in the centre is the only fireplace. Scarcely anything worthy of the name of agriculture is carried on, and their chief care is devoted to their corn and goats. Lazy, dirty, untruthful, living without a thought beyond the present, capable of any crime for the sake of drink, it seems no great pity that the tribe is dying out. Crossing the Vaal River, Klip drift was reached; in the district between the Vaal and Harts Rivers herds of the striped grey gnu (*Catoblepas gorgon*) were to be seen. The gnus were here no better than the channels of boulder-strewn. Formerly both shores of the lower part of the Harts River were in the possession of Yantje, the Batlapin chief, who is a dependant of the British with an income of 200*l.* a year. This chief now resides at Likatlong. The Batlapins are mostly of middle height, not so tall as the Zulus nor so powerfully built as the Fingos. Their complexions are bright and clear; they have very wide noses.

The sugar-cane was cultivated here and there, but the only use made of it was the chewing the more juicy portions of the stem. After Klipdrift, Bloemhof was visited; then the Maquassie River was crossed, and a few days were spent at Klipspruit, which would seem to be quite a paradise for the sportsman; the early morning hours never failed to exhibit many herds of gnus and antelopes. The bushes were the haunt of the guinea fowl. This breed of wild fowl is one of great interest; though hunted perpetually, it would appear to be still on the increase; most frequently it is found in flocks of from ten to forty in number.

Arriving at Wonderfontein, the underground fissures, sometimes several miles long, were examined. One fine cave, known as the "Grotto of Wonderfontein," was partially explored; a little brook rippled through it, and it was thickly inhabited by bats. After much enjoyment of the natural objects associated with this place, Dr. Holub determined to end here his first excursion, and from thence to make his way back to Dutoitspan; slightly altering his track back, he broke somewhat new ground. Here is a short account of an encounter with a mass of feathered life:—

"The bank on which we crouched was the boundary of a depression overgrown with grass and reeds, but now full of rain-water. In this pool were birds congregated in numbers almost beyond what could be conceived—birds swimming, birds diving, birds wading. Perhaps the most conspicuous were the sacred ibises, of which there would not have been less than fifty, some of them standing asleep with their heads under their wings, some of them striding about solemnly, pausing every now and then to make a snap at a smaller victim, and some of them hurrying to and fro, dipping their bills below the water in search of fish. On the far side, as if utterly oblivious of the world, a pair of grey herons stood pensive and motionless. From amongst the weeds, rose the unabated cackle of wild ducks, grey and speckled. Mingling with this were the deep notes of the countless moorhens, while an aspect of perpetual activity was given to the pond by the nimble movements of swarms of little divers. At a spot where the bank descended somewhat sharply to the edge of the pool several ruffs were wandering backwards and forwards, uttering their peculiar shrill whistle, and large flocks of sandpipers were to be noticed, either skimming from margin to margin of the water or resting passively just where they had alighted. The explanation of this enormous concourse of the feathered tribe was very simple. A storm of unwonted violence had washed down from the plain above into the hollow beneath myriads of worms, insects, lizards, and even mice, and so bountiful a banquet had attracted the promiscuous and immense gathering which had excited my wonder."

The second excursion was begun under somewhat better auspices, but it was only contemplated to journey over half the distance between the Diamond Fields and

the Zambesi. The expedition started in November, 1873, with four Europeans, a waggon and eight oxen, with a Griqua driver, a saddle-horse, and nine dogs. From Dutoitspan it first went to Musemanyana, which is the most northerly possession of the Koranna king of Mamusa. On the north and east it is bounded by plains abounding in game, to which the author gave the name of the "Quagga flats." They belong to Montsua, and are the common hunting grounds of Batlapins, Barolongs, Korannas, and the Dutch farmers from the Western Transvaal. From Musemanyana they journeyed to Moshaneng. At Konana they found an immense abundance of game: gnus, blessbocks, hartebeests, springbocks, and zebras grazed in herds. A very interesting account is given of Molema's town: the sale of brandy is prohibited; European cereals have been introduced; two missionaries were found here. Moshaneng is a Bechuana town, with a population of some 7000, many of whom have given up their heathen rites. Moloapolole was the next place visited. It was the residence of King Sechele, of whom we have lately heard a good deal. The number of his subjects was then estimated at about 35,000, while resident but non-tributary tribes amounted to from 18,000 to 20,000 more.

Dr. Holub describes the king, somewhat harshly we think, as looking every inch a hypocrite. The king's house, furnished in European fashion, had cost him some 3000*l*. He was the first of the six Bechuana kings to profess Christianity, but for all that he evidently is a believer in the doctrine that "the end justifies the means." Tea was served in cups; it was good, and the cakes unexceptionable; the sugar-basin, &c., were all of silver.

Fig. 2.

The king evidently enjoyed his tea, of which he swallowed nearly a quart. Addressing the king, Dr. Holub said: "When I was only thirteen years of age I read your name in Nyaka Livingstone's book. I little thought then that I should ever see you to speak to you; far more surprising is it to me to find myself drinking tea in your palace." The king, although still said to practise rain magic, replied sanctimoniously, "His ways are past finding out."

The Barwas and the Masarwas, although perhaps not really identical, are known by either name promiscuously amongst the Northern Bechuanas. They may be described as a cross between some branches of the Makalahari and the Bushmen. Their form, complexion, language, and customs afford various indications of their double origin. They are adepts at hunting, and are employed as hunters by their Bechuana masters. They use bows and arrows, and are very adroit in capturing animals by means of poisoned assegais. Their huts look something like large haycocks, consisting of a framework of stakes driven into the earth, fastened together firmly at the top, about five feet from the ground, and covered with a layer of twigs and dry grass. The Masarwas are of medium height, reddish-brown complexion, and a repulsive cast of countenance. They have a great aversion to agriculture and to cattle-breeding. They do not practise stone carving or use any stone utensils. They are very superstitious; treat their wives well, and show a great regard for their dogs. They pierce the nasal cartilage on reaching maturity; wear a body-cloth of hide. They suffer much from cold; but instead of lighting fires in their huts like the Korannas, regularly light them in the open air. The accompanying illustration shows these Masarwas at home.

From Molopole the route lay to Shoshong. This was

the northern limit of this journey. It is the capital of the Eastern Bamangwatos, and the most important town in any of the independent native kingdoms in the interior of South Africa. It lies on the River Shoshon. The king's residence was built around the Kotla; the place has a circular space inclosed by a fence of strong stakes, the entrance being on the south side, opposite to which was an opening leading to another smaller inclosure, which was the king's cattle kraal, where his farm stock was kept at night, the horses being accommodated in the

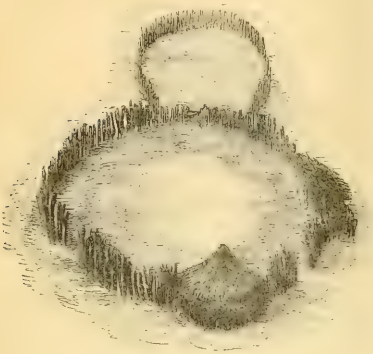

Fig. 3.

Kotla itself. Every night the entrances are made secure with stakes. Fig. 3 shows the king's kotla at Shoshong.

According to the missionary's (Mr. Mackenzie's) estimate, King Sekhomo's actual revenue was equivalent to about 3000*l.* a year, and consisted of cattle, ivory, ostrich-feathers, and skins; he had—happy man!—no state expenditure whatever. Dr. Holub's second expedition ended on April 7, when he arrived in safety with his large collections at Dutoitspan.

(*To be continued.*)

THE NEW INSECTARIUM IN THE ZOOLOGICAL SOCIETY'S GARDENS

ALTHOUGH of late years many entomologists have been in the habit of rearing insects in captivity for the purpose of watching their transformations and obtaining good specimens in each stage of existence, nothing like a systematic attempt, so far as we know, has been made to form a general collection of living insects for exhibition. As in former days as regards reptiles and the lower marine animals, so in the present instance as regards its insectarium, our Zoological Society seems to be first in the field; and so far as we can judge from the progress already made, to be likely, if not altogether successful, to attain many interesting and instructive results.

The building in the Regent's Park Gardens now used as an insectarium is constructed of iron and glass on three sides, with a brick back to it, and formerly formed part of the refreshment buildings. It was moved to its present site, on the north bank of the canal near the north entrance, last autumn, and has been used during the winter as a nursery for delicate monkeys and tropical birds. The cases containing the insects, to which it is now devoted, are arranged on stands all round the building, and also occupy two tables in the centre. The cases used for the principal specimens are formed of zinc plates. The upper part of them is glazed on all four sides, the top being formed of perforated zinc so as to admit the air. The food-plant or object required for the suspension of the chrysalises, when that stage of the insect is exhibited, is inserted into the case through a circular hole in the bottom, but the glass front also opens, so that ready access may be obtained to the interior. The larger cases in the front row measure about 24 inches in breadth by 18 in depth, and are 32 inches in height. The cases in the opposite row are of similar construction, but rather smaller in dimensions.

The cases on the south side (on each side of the entrance door) are mostly appropriated to the exhibition of the larger and finer species of silk-producing moths of the family Bombycidæ. Amongst them may be specially noticed Glover's Silk-moth (*Samia Gloveri*) and the Cercopian Silk-moth (*S. cecropia*) of North America, Perny's Silk-moth (*Attacus Pernyi*) of Northern China, the Tusseh Silk-moth (*A. mylitta*) of India, and the great Emperor Moth (*Saturnia pyri*) of Europe. These have been imported from their native countries in the stage of chrysalis. Of the first three above named, many examples are already hatched, and the splendid *imagines*, or perfect insects, are appearing one by one. Soon after appearing the sexes unite and eggs are produced, after which the parents quickly perish. The fertilised eggs remain to produce caterpillars, which will eventually form a second set of pupæ or chrysalises and thus continue the species.

On the north side of the Insectarium the smaller cases are devoted principally to the rarer and more noticeable moths and butterflies of Europe, such as the Swallow-tailed Butterfly (*Papilio machaon*), the Black-veined Butterfly (*Aporia cratægi*), the Purple Emperor (*Apatura iris*), and the Orange-tip (*Anthocharis cardamines*) among the former, and the Scarlet Tiger Moth (*Callimorpha dominula*) and Emperor Moth (*Saturnia carpini*) among the latter group. The series is continued, mixed with other forms, at the east end of the building. On the large tables in the middle of the Insectarium are examples of other butterflies, moths, beetles, mayflies, stoneflies, and aquatic insects of different kinds, all well worthy of attention and study. The whole series exhibited now contains examples of about fifty species, but daily additions are made to it.

Finally we should mention that every specimen in the Insectarium is distinctly labelled, and that over each of the principal cases is fixed a glazed box, in which are placed preserved specimens of the various stages of metamorphosis of the insect exhibited in the case beneath.

Nor must we forget to add that the Insectarium is under the sole charge of Mr. E. Watkins, an experienced entomologist and breeder of insects, whose name is well known to many naturalists. Mr. Watkins, whose services have been secured for the Zoological Society for the purpose of inaugurating this interesting exhibition, is in daily attendance at the Insectarium, and is most ready and willing to afford information and instruction to all who apply to him.

NOTES

THE numerous friends and still more numerous admirers of Prof. Gegenbaur will be glad to hear that he is now believed to be out of danger. It appears that the illness of the distinguished anatomist commenced with an attack of erysipelas, the origin of which is not known; it does not seem that the case was complicated by any blood poisoning, but there was an attack of peritonitis, which caused the very greatest anxiety for some days. Lately however his condition has considerably improved, but it will, of course, be a long time before he can be completely restored to health.

AT the *conversazione* given to Prof. Helmholtz at University College, Mr. Latimer Clark exhibited the accompanying

interesting unpublished letter from Sir Isaac Newton to Dr. Law :—

"*London, Dec.* 15, 1716

"Dear Doctor: He that in ye mine of knowledge deepest diggeth, hath, like every other miner ye least breathing time, and must sometimes at least come to terr; alt for air.

"In one of these respiratory intervals I now sit doune to write to you, my friend.

"You ask me how, with so much study, I manage to retene my health. Ah, my dear doctor, you have a better opinion of your lazy friend than he hath of himself. Morpheous is my best companion; without 8 or 9 hours of him yr correspondent is not worth one scavenger's peruke. My practizes did at ye first hurt my stomach, but now I eat heartily enow as y' will see when I come down beside you.

"I have been much amused by ye singular φενομενα resulting from bringing of a needle into contact with a piece of amber or resin fricated on silke clothe. Ye flame putteth me in mind of sheet lightning on a small—how very small—scale. But I shall in my epistles abjure Philosophy whereof when I come down to Sakly I'll give you enow. I began to scrawl at 5 mins frn 9 of ye clk, and have in writing consmd 10 mins. My Ld. Somerset is announced.

"Farewell, Gd bless you and help yr sincere friend

"(Signed) ISAAC NEWTON

"To Dr. Law, Suffolk"

VERY great progress is being made in Paris to render the forthcoming Electric Exhibition a success. There are sixty-four English exhibitors. The Post Office is going to make a very good display, and as the old apparatus of Ampère and Œrsted will be shown, it is hoped that those of Faraday and Wheatstone will be added.

L'Électricien is the title of a new fortnightly journal published in Paris and devoted to the interests of the science of electricity. It might have been thought that with *L'Électricité*, edited by M. Wilfrid de Fonvielle, and *La Lumière Électrique*, edited by M. le Comte du Moncel, appearing every week, the field would have been fully occupied. The latter journal is however somewhat more special in its aims, and the former appears to be at present given over to discursive maunderings on natural photophony and to rabid attacks upon Clerk-Maxwell's theory of electricity. At any rate there appears to be scope for a journal of a somewhat different order; and the pages of No. 1, now before us, contain valuable contributions from well-known pens. M. Mercadier contributes an article on the use of selenium in the photophone; M. Niaudet-Breguet writes upon the different systems adopted for central stations in telephone exchanges; Dr. de Cyon has an interesting article on electrobiology; M. Gaston Tissandier discourses on one of the domestic applications of electricity; while Prof. C. M. Gariel contributes a valuable discussion of the graphic method of representing Ohm's law and other laws of current electricity. The acting editor is M. E. Hospitalier, the well-known electrical engineer. The publication, which is illustrated, is got up in admirable style by the house of Gustave Masson. We wish all success to the undertaking so excellently begun.

THE Paris Municipal Laboratory for testing all matters having any bearing on health, and the organisation of which is now quite complete, was opened to the public on March 1. The establishment, which is situated at the Prefecture of Police, Quai du Marché Neuf, will be formally inaugurated to-morrow. The laboratory is already regarded as a success, the number of objects presented for analysis amounting in April to not less than 700, mostly wine purchased in shops, and suspected of being adulterated. The number of falsifications amounts to 80 out of 100. In every case where adulteration has been detected the results have been communicated to the competent authorities, who have prosecuted. Milk has been also sent in great quantity, and in many cases proved adulterated or mixed with water. The results of these inquiries have created such an agitation among Parisian milkmen that when they were surrounded at Batignoles Terminus and their boxes about to be opened for inspection, they resisted. A scuffle ensued between them and the police, and the result was that a number escaped. French chocolate has also been found very defective in quality, an immense number of substances having been added to it. The head of this new service is M. Ch. Gerard, a chemist of reputation. All the assistants are selected by competitive examination, and are only to remain in the service for a few years. They belong mostly to the School of Medicine and Pharmacy, so that the institution may be considered as a public school of practical chemistry. The general organisation is said to be modelled after the Chemical Laboratory at South Kensington. Notable features are the use of spectroscopic analysis combined with the electric spark, a workshop for photography, and the special service for trichinæ. The ordinary market-inspectors are trained to use special microscopes for that purpose. A special instrument has been constructed for boring in ham small holes which are not visible when cooked, and the particles of flesh so extirpated are analysed microscopically. A special apparatus has been designed and is in constant use for trying swine, and even the muscles of patients.

MR. MORRIS, the Director of Public Gardens and Plantations in Jamaica, has recently issued a pamphlet entitled "Notes on Liberian Coffee, its History and Cultivation." In this pamphlet Mr. Morris has brought together a great deal of valuable matter connected with this remarkable species of *Coffea*, which will prove not only interesting to those who wish to see the resources of our Colonies developed, but particularly to those about to embark in the cultivation of coffee as an article of commerce. The pamphlet commences with some historical remarks on the species, and then touches on its introduction into Jamaica, followed by a consideration of the plant as found in Liberia, in the West and East Indies, of its propagation and the establishing of plantations with regard to climate, soil, and various other details; some interesting notes follow on the yield of Liberian coffee trees, and of the commercial value of the coffee itself. In view of this pamphlet being of considerable use to persons abroad who may be about to embark in the cultivation of this particular species, we may say that it is issued from the Government Printing Establishment at Jamaica, and that its price is sixpence.

A NEW medicinal oil has just been introduced into this country by Messrs. Burgoyne and Burbidges, the well-known chemists of Coleman Street. It is known as Oolachan oil, and is said to be scarcely distinguishable from cod liver oil. It is obtained from a fish called by the North American Indians Oolachan, or candle fish, from the fact that when dried the fish itself can be used as a torch or candle on account of the large quantity of oleaginous matter it contains. The fish is met with on the coasts of Vancouver's Island and British Columbia, and in the bays between the Frazer and Skuna Rivers. Similar in its habits to the salmon, it ascends the rivers to spawn once a year, but remains only for a very short period, sometimes not more than a day, and as this is the only time they can be caught by the Indians, the manufacture of the oil is somewhat precarious. The fish itself, which is about the size of a herring, is much esteemed by the Indians on account of its delicacy of flavour and valuable medicinal properties. In America the oil has already a great reputation as a valuable and efficient substitute for cod liver oil, and there is every probability as it becomes known in this country of its taking a prominent place as an important medicine.

M. HERVÉ-MANGON, the director of the Conservatoire des Arts et Métiers, has established a manufacture of pottery in the large hall, in order to make the Parisian public acquainted with several of the manipulations used in the large manufactories. This demonstration, which will be continued during several

Sundays, bears principally on the use of the lathe for modelling. M. Hervé Mangon, having established a Siemens electro-magnetic machine for lighting purposes at the Conservatoire, sends by request supplies to the several laboratories of the establishment. Up to the present moment it has been used only by photographers.

At the adjourned ordinary meeting of the Sanitary Institute, to be held at 9, Conduit Street, on Wednesday, May 18, at 8 p.m., the discussion will be continued upon the address delivered by Dr. Richardson, F.R.S., Chairman of Council—"Suggestions for the Management of Cases of Small Pox, and of other Infectious Diseases in the Metropolis and Large Towns."

At the meeting of the Iron and Steel Institute last week the papers were almost entirely of a purely technical or commercial character.

Mr. Charles E. Turner, Lector at the University of St. Petersburg, will begin a course of five lectures at the Royal Institution, on the Great Modern Writers of Russia—Pouschkin, Lermontoff, Gogol, Tourgenieff and Nekrasoff—on Saturday, the 21st.

An International Medical Congress meets at Madrid on the 20th inst.

The extinction of the Brush electric light in the City last week is stated to have been caused by the defective insulation of the wires.

All the large railway companies in the country have intimated their intention of sending engines to the typical engine exhibition to be held at Newcastle on the occasion of the Stephenson centenary.

The annual meeting of the U.S. Society for the Promotion of Agricultural Science will be held at Cincinnati on Tuesday, August 16, the day preceding the session of the American Association for the Advancement of Science.

The fifth and concluding course of Cantor Lectures for the present session at the Society of Arts will be by Mr. R. Brudenell Carter, on the subject of "Colour Blindness, and its Influence on Various Industries." The course consists of three lectures, the first of which will be delivered upon Monday next, the 16th inst. This lecture will deal generally with the subject. The second lecture will treat of methods of testing for colour blindness, the prevalence of the affection, mistakes of the colour blind, and methods of endeavouring to counteract the defect. The subject of the third lecture is specially the industries chiefly affected by colour blindness. In it an account will be given of recent legislation on the subject in America, and the necessity for it in this country.

Masson of Paris has issued a third series of Prof. Paul Bert's "Revues scientifiques," published in the *République Française*.

The Annual Report of the Belfast Naturalists' Field Club for 1879-80 tells of its continued prosperity, and contains an account of the various excursions made during last summer. Appended are "A List of the Post-Tertiary Foraminifera of the North-East of Ireland," by Joseph Wright, F.G.S., and "A List of the Mollusca of the Boulder Clay of the North-East of Ireland," by S. A. Stewart.

The Birmingham Natural History Society has issued a *Report and Transactions* for 1880, which in quantity and quality does its members great credit. There is an interesting address by the president, Mr. W. Southall, and a number of natural history papers, some by outsiders, and one or two on subjects connected with local natural history. The Society is now housed in the Mason College.

In compliance with the provisions of a recent decree, the system of Algerian telegraphy has been *rattaché* to the French administration, and is governed from Paris. The head of the Algerian service has been appointed director at Lyons.

The annual *conversazione* given by the President and Council of the Royal Society was held on Wednesday last week. It was well attended, and there were numerous scientific and artistic novelties on view.

Mr. E. im Thurm is writing on Aspects of Plant Life in British Guiana, in the *Gardeners' Chronicle*.

The additions to the Zoological Society's Gardens during the past week include a Black-faced Spider Monkey (*Ateles ater*) from Eastern Peru, a Collared Peccary (*Dicotyles tajaçu*) from South America, presented by Mr. E. H. Dance; a Roseate Cockatoo (*Cacatua roseicapilla*) from Australia, presented by Sir Charles C. Smith, Bart.; a Swift (*Cypselus apus*), European, presented by Mr. H. H. Johnston; a Common Viper (*Vipera berus*), British, presented by Mr. John Poyer Poyer.

OUR ASTRONOMICAL COLUMN

The Comet of 1812.—Under certain suppositions as regards the epoch of perihelion passage of this comet, the return of which may now be expected, it will be necessary to search for it on a particular date, upon the assumption that it has yet a considerable orbital angle to describe before arriving in perihelion, because the geocentric position corresponding to a small orbital angle will place the comet too near to the sun's position to allow of observations. If we employ the elliptical elements deduced by Mr. W. E. Plummer from a new reduction and discussion of several of the most reliable series of observations in 1812, we find the following values of the comet's heliocentric equatorial co-ordinates and of the radius vector for intervals of 100 days to 60 days before perihelion passage; the co-ordinates are referred to the equinox of 1881·0.

Time from perihelion.	x.	y.	z.	Log. radius-vector.
− 100 days	+0·5619	−0·5939	+1·6649	0·2683
− 90 ,,	+0·5478	−0·4432	+1·5725	0·2363
− 80 ,,	+0·5305	−0·2904	+1·4712	0·2016
− 70 ,,	+0·5093	−0·1357	+1·3592	0·1637
− 60 ,,	+0·4832	+0·0209	+1·2337	0·1222

Combining these co-ordinates with the X, Y, Z of the *Nautical Almanac* for May 27·5 and June 26·5, days of new moon in the present year, we get the following results:—

For May 27·5

t.	R.A.	Decl.	Distance from earth.	Intensity of light.
− 100 days	15°·2	+63°·9	2·267	0·057
− 90 ,,	23·5	62·0	2·201	0·070
− 80 ,,	31·2	59·4	2·140	0·086
− 70 ,,	38·3	56·2	2·083	0·108
− 60 ,,	44·8	+52·2	2·030	0·139

For June 26·5

t.	R.A.	Decl.	Distance from earth.	Intensity of light.
− 100 days	35°·7	+74°·5	2·146	0·063
− 90 ,,	47·1	71·4	2·084	0·078
− 80 ,,	55·8	67·6	2·027	0·096
− 70 ,,	62·5	63·1	1·976	0·120
− 60 ,,	67·8	+57·9	1·931	0·153

These places will define the region of the sky where the comet should be sought, and telescopes of good optical capacity will be needed. When Pons discovered the comet on July 20, 1812, the theoretical intensity of light was 0·18.

The mean motion in 1812 not being ascertainable within very narrow limits, no attempt, so far as we know, has been made to determine the effect of perturbation in the present revolution, and we have therefore to be content with the method of careful sweeping over the region of the sky, on which the orbit may be projected at any time. Sir George Airy's orbit-sweeper, it is true, would limit the extent of sky-ground to be examined, but we suspect the only instrument of sufficient power yet mounted upon his principle is that at the Imperial Observatory at Strassburg, where it is not to be doubted that it will be put in active operation by Prof. Winnecke. We may remind the reader that

sweeping ephemerides for the whole year were published from Strassburg some time since, and will be found in the *Vierteljahrsschrift der Astronomischen Gesellschaft*, Jahrgang 12. Those given above apply to greater distance from perihelion.

THE TRANSIT OF VENUS, 1882.—At the sitting of the Paris Academy of Sciences, on the 2nd inst., the Minister of Foreign Affairs transmitted a letter from the British Ambassador, on the part of his Government, desiring to be informed with which French authorities the Royal Society of London should communicate, with the view to an interchange of opinions relative to the observation of the approaching transit of Venus. The letter was referred to a commission already nominated.

COMET 1880, V. (PECHÜLE, DECEMBER 16).—This comet was followed by M. Bigourdan until March 31, efforts having been made at the Observatory of Paris to observe it as long as possible on account of the resemblance of the orbit to that of the great comet of 1807. M. Bigourdan's last elements gave the place with errors of only 2s.·0 in right ascension, and 20″ in declination: they will be found in *Comptes rendus*, vol. xcii. p. 172.

COMET 1881, *a* (SWIFT, MAY 1).—We have received from the Imperial Observatory of Strassburg the following observation of the new comet, made by Dr. Hartwig with the "orbit-sweeper":—

May 5, at 14h. 56m. 9s.·8 mean time at Strassburg.
Right Ascension 0h. 19m. 17s.·76; Declination +32° 19′ 32″·3.

CHEMICAL NOTES

IN the *American Chemical Journal* Prof. Mallet describes a simple form of calorimeter whereby the specific heats of moderately small quantities of solids or liquids may be measured with a fair degree of accuracy. Mercury is employed, instead of water, as the material whose temperature is raised, and comparison is made, not of the total amounts of heat given out by different bodies on cooling, but of fractions of this heat rendered as nearly as possible equal.

IN *Compt. rend.* Berthelot gives several thermal measurements showing that in the substitution of halogens for hydrogen in hydrocarbons, the quantity of heat evolved varies according to the series and chemical function of the hydrocarbons employed, and is generally smaller the greater the number of halogen atoms substituted. The heat of formation of chloral alcoholate in various physical states is also considered by Berthelot: among other results it is shown that chloral hydrate is decomposed by an excess of absolute alcohol, but that the alcoholate is decomposed by much water; in the former of these actions there is exhibited the decomposition of a more volatile compound—chloral hydrate—and formation of a less volatile—chloral alcoholate; and at the same time the expulsion of a less volatile substance—water—by a more volatile—alcohol.

THE proto-salts of chromium (or chromous salts) are unstable and but little known: in *Compt. rend.* M. Moissan describes two salts belonging to this series, viz., chromous chloride, $CrCl_2$, and chromous sulphate, $CrSO_4 7H_2O$.

IN the *Berichte* of the German Chemical Society Herr C. Zimmermann states that potassium permanganate may be used for determining iron in presence of considerable quantities of hydrochloric acid, if a solution of manganous chloride, or preferably manganous sulphate, be added previous to titration.

ACCORDING to the hypothesis of Vant' Hoff, propyl glycol ought to be an optically active liquid, inasmuch as the molecule of this compound contains one *asymmetric* carbon atom, *i.e.* an atom directly united with four different radicles;—propyl glycol being formulated as $CH_3—\underset{\displaystyle H}{\overset{\displaystyle /\!\!\diagdown}{C}}—CH_2OH$. Le Bel has recently shown (*Compt. rend.*) that if ordinary propyl glycol—from glyceric acid—be subjected to partial fermentation, the unfermented residue exhibits slight dextrorotatory powers. Le Bel thinks that ordinary propyl glycol contains both an optically active and an optically inactive modification, and that the latter being decomposed by the ferment, the presence of the former is rendered evident. From optically active propyl glycol Le Bel has prepared an active propylene oxide boiling at 35°, which he states is the most volatile optically active compound at present known.

A SERIES of optically active amylamines is described in *Compt. rend.* by M. Plimpton. The compounds are obtained from amyl bromide—from active amylic alcohol—by the action of alcoholic ammonia.

IN *Chem. Centralblatt* E. Ludwig describes experiments on the localisation of arsenic, absorbed as arsenious oxide, in the animal organism: contrary to the results of many former experimenters, Ludwig asserts that an accumulation of arsenic occurs in the liver: neither the bones nor the brain retain arsenic for any length of time. Arsenic was detected in the liver of a dog forty days after the last dose had been administered, but no trace could be found in the brain, bones, or muscles. Ludwig's results are generally confirmed by Johnson and Chittenden (*Amer. Chem. Journ.*).

MM. DES CLOIZEAUX AND DAMOUR describe (*Compt. rend.*) a new selenite of copper, to which they give the name *Chalcomenite*. The mineral occurs in the Argentine Republic, in small green clinorhombic crystals, associated with selenite of lead, and selenite of lead and copper.

M. SULLIOT proposes (*Compt. rend.*) to employ "chamber crystals" as a disinfectant. He places a solution of these crystals in sulphuric acid in the room or other place to be disinfected; the atmospheric moisture slowly decomposes the liquid with liberation of oxides of nitrogen, which destroy noxious organic matter present in the air.

MR. M. W. WILLIAMS describes, in *Chem. Soc. Journal*, a method for freeing water, to be analysed by the process of Frankland and Armstrong, from nitrates and ammonia. He digests the water with carefully-prepared "copper-zinc couple," whereby all nitrates are reduced to ammonia; he then distils off ammonia, evaporates to dryness, and proceeds in the usual manner. The use of sulphurous acid, which has always been much objected to, is thus obviated.

IN the same journal there is a suggestive paper by Prof. Hartley on the "Relation between the molecular structure of carbon compounds and their absorption-spectra." Evidence is accumulated in favour of the view that the selective absorption exhibited by "aromatic" compounds depends on the vibrations of the carbon atoms within the molecule, but that these atomic vibrations are dependent upon the nature of the molecular vibrations themselves, and are probably to be regarded as harmonics of these fundamental vibrations.

THE second and third parts of the *Gazetta Chimica Italiana* for the present year exhibit very unmistakably the activity of Italian chemists, chiefly in the domain of organic chemistry. Schiff continues his researches on Glucosides; the derivatives of thymol are studied by Paternò and Canzoneri; Macagno describes experiments on the spectroscopic detection of artificial colouring matters in wines. Koenig, Schiaparelli, Barbaglia, and other known chemists contribute papers.

GEOGRAPHICAL NOTES

MR. EDWARD WHYMPER on Monday last addressed a large meeting of the Geographical Society on some features in his recent journey among the Great Andes of the Equator. His paper was not, however, of so popular a nature as those which he read before the Alpine Club and the Society of Arts. The chief facts left on the minds of his very attentive audience may be briefly stated. Mr. Whymper found by careful experiments that aneroid barometers are not to be depended upon for the determination of heights, and that there is a remarkable difference in altitudes as fixed by the boiling point of water and the mercurial barometer. He asserted, as the result of his observations, that it is a mistake to suppose that there are two parallel chains in the Ecuadorian Andes, as usually shown on our maps. This is a point, however, on which more light is evidently required. Mr. Whymper's account of his ascent of the hitherto unknown peak called Sara-Urcu, was very interesting, and this achievement alone would stamp him a mountaineer of the highest skill and courage.

THE following award has just been made of the medals given annually by the Council of the Geographical Society for competition among a limited number of public schools:—Physical Geography (Mr. H. N. Moseley, F.R.S., examiner): Gold medal, E. G. Reid, Dulwich College; silver medal, Sydney Edkins, City of London School; Political Geography (Right Rev. Bishop Abraham, examiner): Gold medal, Theodore

Brooks, London International College ; silver medal, Chas. Th. Knaus, Dulwich College.

THE *Willem Barents*, the little Polar ship which has already made three voyages to the Northern Polar Sea, has left Amsterdam for the fourth time. The crew consists of a lieutenant of the Royal Navy, H. van Broekhuyzen, as captain, two other officers, a physician, a zoologist, a photographer (the Englishman, Mr. Grant), and six sailors.

DOCTORS ARTHUR AND AUREL KRAUSE have left Bremen to spend some time in the neighbourhood of Behring Straits for the purpose of exploring and collecting, at the expense of the Bremen Geographical Society. They will visit the Chukchi peninsula, Behring Islands, and Alaska, where they will make zoological collections and carry on various scientific observations.

MR. HENRY SOLTAU and Mr. J. W. Stevenson, of the China Inland Mission, have successfully made the journey from Bhamo into China, reaching I-chan-fu, on the Yang-tsze-kiang, on March 14. This is the first time that it has been accomplished by Europeans, and the time occupied was about four months.

THE first paper in the May number of *Petermann's Mittheilungen* is a study of the Padolian Dniester region by Ritter v. Habdank Dumkowski. This is followed by the continuation of Dr. Radde's account of his journey to Talysh, Aderbeijan and the Sawalan ; M. Charnay's expedition to Central America from the *North American Review* ; M. Potanin's researches in Western Mongolia in 1876-77, with a map ; Recent Surveys in the Western United States, with a map ; and the usual Monthly Notes. Among the latter is a long account of Dr. Lenz's journey to Timbuctoo, with a sketch-map.

WE have received Nos. 1 and 3 of the *Bulletin* of the American Geographical Society, the two most important papers in which are on the recent investigations of the Gulf Stream, by the U.S. Coast Survey steamer *Blake*, by Commander J. R. Bartlett, and Changes in the Physical Geography of the Ancient Home of Man in Central and Western Asia, by the Rev. Owen Street.

DR. MOFFAT, the venerable missionary and pioneer explorer in Africa, was entertained at a banquet in the Mansion House on Saturday.

THE *Bulletin* of the Society of Commercial Geography of Bordeaux contains a brief statement of M. Paul Soleillet's views on the African question. After addressing the Society M. Soleillet proceeded to Paris, but he entertains hopes of being able to return to West Africa in November.

THE PRODUCTION OF SOUND BY RADIANT ENERGY[1]

IN my Boston paper on the photophone (NATURE, vol. xxii. p. 500) the discovery was announced that thin disks of very many different substances *emitted sounds* when exposed to the action of a rapidly-interrupted beam of sunlight. The great variety of material used in these experiments led me to believe that sonorousness under such circumstances would be found to be a general property of all matter.

At that time we had failed to obtain audible effects from masses of the various substances which became sonorous in the condition of thin diaphragms, but this failure was explained upon the supposition that the molecular disturbance produced by the light was chiefly a surface action, and that under the circumstances of the experiments the vibration had to be transmitted through the mass of the substance in order to affect the ear. It was therefore supposed that if we could lead to the ear air that was directly in contact with the illuminated surface, louder sounds might be obtained, and solid masses be found to be as sonorous as thin diaphragms. The first experiments made to verify this hypothesis pointed towards success. A beam of sunlight was focussed into one end of an open tube, the ear being placed at the other end. Upon interrupting the beam, a clear musical tone was heard, the pitch of which depended upon the frequency of the interruption of the light and the loudness upon the material composing the tube.

While in Paris a new form of the experiment occurred to my mind, which would not only enable us to investigate the sounds produced by masses, but would also permit us to test the more general proposition that sonorousness, under the influence of intermittent light, is a property common to all matter. The substance to be tested was to be placed in the interior of a transparent vessel made of some material which (like glass) is transparent to light but practically opaque to sound.

Under such circumstances the light could get in, but the sound produced by the vibration of the substance could not get out. The audible effects could be studied by placing the ear in communication with the interior of the vessel by means of a hearing tube.

Some preliminary experiments were made in Paris to test this idea, and the results were so promising that they were communicated to the French Academy on October 11, 1880, in a note read for me by Mr. Antoine Breguet.

I wrote to Mr. Tainter suggesting certain experiments, and upon my return to Washington in the early part of January, Mr. Tainter communicated to me the results of the experiments he had made in my laboratory during my absence in Europe. He had commenced by examining the sonorous properties of a vast number of substances inclosed in test-tubes in a simple empirical search for loud effects. He was thus led gradually to the discovery that cotton-wool, worsted, silk, and fibrous materials generally, produced much louder sounds than hard rigid bodies like crystals, or diaphragms such as we had hitherto used.

In order to study the effects under better circumstances he inclosed his materials in a conical cavity in a piece of brass closed by a flat plate of glass. A brass tube leading into the cavity served for connection with the hearing-tube. When this conical cavity was stuffed with worsted or other fibrous materials the sounds produced were much louder than when a test-tube was employed. Mr. Tainter next collected silks and worsteds of different colours, and speedily found that the darkest shades produced the best effects. Black worsted especially gave an extremely loud sound.

About a teaspoonful of lamp-black was placed in a test-tube and exposed to an intermittent beam of sun-light. The sound produced was much louder than any heard before. Upon smoking a piece of plate-glass, and holding it in the intermittent beam with the lamp-black surface towards the sun, the sound produced was loud enough to be heard, with attention, in any part of the room. With the lamp-black surface turned from the sun the sound was much feebler.

Upon smoking the interior of the conical cavity and then exposing it to the intermittent beam with the glass lid in position as shown, the effect was perfectly startling. The sound was so loud as to be actually painful to an ear placed closely against the end of the hearing-tube. The sounds, however, were sensibly louder when we placed some smoked wire gauze in the receiver.

When the beam was thrown into a resonator, the interior of which had been smoked over a lamp, most curious alternations of sound and silence were observed. The interrupting disk was set rotating at a high rate of speed, and was then allowed to come gradually to rest. An extremely feeble musical tone was at first heard, which gradually fell in pitch as the rate of interruption grew less. The loudness of the sound produced varied in the most interesting manner. Minor reinforcements were constantly occurring, which became more and more marked as the true pitch of the resonator was neared. When at last the frequency of interruption corresponded to the frequency of the fundamental of the resonator, the sound produced was so loud that it might have been heard by an audience of hundreds of people.

The extremely loud sounds produced from lamp-black have enabled us to demonstrate the feasibility of using this substance in an articulating photophone in place of the electrical receiver formerly employed. Words and sentences spoken into the transmitter in a low tone of voice were audibly reproduced by the lamp-black receiver at forty metres distance.

In regard to the sensitive materials that can be employed, our experiments indicate that in the case of solids the physical condition and the colour are two conditions that markedly influence the intensity of the sonorous effects. The loudest sounds are produced from substances in a loose, porous, spongy condition, and from those that have the darkest or most absorbent colours. The materials from which the best effects have been produced are cotton-wool, worsted, fibrous materials generally, cork, sponge, platinum and other metals in a spongy condition, and lamp-black.

The loud sounds produced from such substances may perhaps be explained in the following manner :—Let us consider, for

[1] Abstract of a paper by Prof. Alexander Graham Bell, read before the National Academy of Arts and Sciences, April 21, 1881.

example, the case of lamp-black—a substance which becomes heated by exposure to rays of all refrangibility. I look upon a mass of this substance as a sort of sponge, with its pores filled with air instead of water. When a beam of sunlight falls upon this mass the particles of lamp-black are heated, and consequently expand, causing a contraction of the air-spaces or pores among them. Under these circumstances a pulse of air should be expelled, just as we would squeeze out water from a sponge. The force with which the air is expelled must be greatly increased by the expansion of the air itself, due to contact with the heated particles of lamp-black. When the light is cut off the converse process takes place. The lamp-black particles cool and contract, thus enlarging the air-spaces among them, and the inclosed air also becomes cool. Under these circumstances a partial vacuum should be formed among the particles, and the outside air would then be absorbed as water is by a sponge when the pressure of the hand is removed.

I imagine that in some such manner as this a wave of condensation is started in the atmosphere each time a beam of sunlight falls upon lamp-black, and a wave of rarefaction is originated when the light is cut off. We can thus understand how it is that a substance like lamp-black produces intense sonorous vibrations in the surrounding air, while at the same time it communicates a very feeble vibration to the diaphragm or solid bed upon which it rests.

In his paper read before the Royal Society on March 10 Mr. Preece describes experiments from which he claims to have proved that the effects are wholly due to the vibrations of the confined air, and that the disks do not vibrate at all.

But for reasons stated Mr. Bell concludes that in the case of thin disks a real vibration of the diaphragm is caused by the action of the intermittent beam, independently of any expansion and contraction of the air confined in the cavity behind the diaphragm. Lord Rayleigh has shown mathematically that a to-and-fro vibration, of sufficient amplitude to produce an audible sound, would result from a periodical communication and abstraction of heat, and he says: "We may conclude, I think, that there is at present no reason for discarding the obvious explanation that the sounds in question are due to the bending of the plates under unequal heating" (NATURE, vol. xxiii. p. 274).

[Mr. Bell then describes experiments (devised by Mr. Tainter) which have given results decidedly more favourable, in his opinion, to the theory of Lord Rayleigh than to that of Mr. Preece.]

The list of solid substances that have been submitted to experiment in my laboratory is too long to be quoted here, and I shall merely say that we have not yet found one solid body that has failed to become sonorous under proper conditions of experiment.[1]

The sounds produced by liquids are much more difficult to observe than those produced by solids. The high absorptive power possessed by most liquids would lead one to expect intense vibrations from the action of intermittent light, but the number of sonorous liquids that have so far been found is extremely limited, and the sounds produced are so feeble as to be heard only by the greatest attention and under the best circumstances of experiment. In the experiments made in my laboratory a very long test-tube was filled with the liquid under examination, and a flexible rubber-tube was slipped over the mouth far enough down to prevent the possibility of any light reaching the vapour above the surface. Precautions were also taken to prevent reflection from the bottom of the test-tube. An intermittent beam of sunlight was then focussed upon the liquid in the middle portion of the test-tube by means of a lens of large diameter.

Results

Clear water	No sound audible.
Water discoloured by ink	Feeble sound.
Mercury	No sound heard.
Sulphuric ether *	Feeble, but distinct sound.
Ammonia	,, ,,
Ammonio-sulphate of copper ..	,, ,,
Writing ink	,, ,,
Indigo in sulphuric acid	,, ,,
Chloride of copper *	,, ,,

The liquids distinguished by an asterisk gave the best sounds.

[1] Carbon and thin microscope glass are mentioned in my Boston paper as non-responsive, and powdered chlorate of potash in the communication to the French Academy (*Comptes rendus*, vol. xcl., p. 595). All these substances have since yielded sounds under more careful conditions of experiment.

Acoustic vibrations are always much enfeebled in passing from liquids to gases, and it is probable that a form of experiment may be devised which will yield better results by communicating the vibrations of the liquid to the air through the medium of a solid rod.

The vapours of the following substances were found to be highly sonorous in the intermittent beam:—Water vapour, coal gas, sulphuric ether, alcohol, ammonia, amylene, ethyl bromide, diethylamene, mercury, iodine, and peroxide of nitrogen. The loudest sounds were obtained from iodine and peroxide of nitrogen. I have now shown that sounds are produced by the direct action of intermittent sunlight from substances in every physical condition (solid, liquid, and gaseous), and the probability is therefore very greatly increased that sonorousness under such circumstances will be found to be a universal property of matter.

At the time of my communication to the American Association the loudest effects obtained were produced by the use of selenium, arranged in a cell of suitable construction and placed in a galvanic circuit with a telephone. But the selenium was very inconstant in its action, and from experiments by Dr. Chichester Bell of University College of London, it was found that all the selenium used was tainted with impurities.

Prof. W. G. Adams (*Proceedings* Royal Society, vol. xxiv. p. 163) has shown that tellurium, like selenium, has its electrical resistance affected by light, and we have found that when this tellurium spiral is connected in circuit with a galvanic battery and telephone and exposed to the action of an intermittent beam of sunlight, a distinct musical tone is produced by the telephone.

It occurred to Mr. Tainter before my return to Washington last January that the very great molecular disturbance produced in lamp-black by the action of intermittent sunlight should produce a corresponding disturbance in an electric current passed through it, in which case lamp-black could be employed in place of selenium in an electrical receiver. This has turned out to be the case, and the importance of the discovery is very great, especially when we consider the expense of such rare substances as selenium and tellurium.

We have observed that different substances produce sounds of very different intensities under similar circumstances of experiment, and it has appeared to us that very valuable information might be obtained if we could measure the audible effects produced. For this purpose we have constructed several different forms of apparatus for studying the effects, but our researches are not yet complete. When a beam of light is brought to a focus by means of a lens the beam diverging from the focal point becomes weaker as the distance increases in a calculable degree. Hence if we can determine the distances from the focal point at which two different substances emit sounds of equal intensity we can calculate their relative sonorous powers. Preliminary experiments were made by Mr. Tainter during my absence in Europe to ascertain the distance from the focal point of a lens at which the sound produced by a substance became inaudible. A few of the results obtained will show the enormous differences existing between different substances in this respect.

Distance from Focal Point of Lens at which Sounds become Inaudible with Different Substances

Lamp-black. In receiver the limit of audibility could not be determined on account of want of space. Sound perfectly audible at a distance of	10·00

Mr. Tainter was convinced from these experiments that this field of research promised valuable results, and he at once de-

vised an apparatus for studying the effects, which he described to me upon my return from Europe. [The apparatus has since been constructed, and Mr. Bell gave a detailed description of it.]

The meaning we have uniformly attached to the words "photophone" and "light" will be obvious from the following passage quoted from my Boston paper :—

"Although effects are produced as above shown by forms of radiant energy, which are invisible, we have named the apparatus for the production and reproduction of sound in this way the 'photophone,' because an ordinary beam of light contains the rays which are operative."

To avoid in future any misunderstandings upon this point we have decided to adopt the term "*radiophone*" proposed by M. Mercadier as a general term signifying an apparatus for the production of sound by any form of radiant energy, limiting the words *thermophone*, *photophone*, and *actinophone* to apparatus for the production of sound by thermal, luminous, or actinic rays respectively. M. Mercadier, in the course of his researches in radiophony, passed an intermittent beam from an electric lamp through a prism, and then examined the audible effects produced in different parts of the spectrum (*Comptes rendus*, December 6, 1880). We have repeated this experiment, using the sun as our source of radiation, and have obtained results somewhat different from those noted by M. Mercadier. A beam of sunlight was reflected from a heliostat through an achromatic lens, so as to form an image of the sun upon the slit. The beam then passed through another achromatic lens and through a bisulphide of carbon prism, forming a spectrum of great intensity, which, when focussed upon a screen, was found to be sufficiently pure to show the principal absorption lines of the solar spectrum. The disk-interrupter was then turned with sufficient rapidity to produce from five to six hundred interruptions of the light per second, and the spectrum was explored with the receiver, which was so arranged that the lamp-black surface exposed was limited by a slit, as shown.

Under these circumstances sounds were obtained in every part of the visible spectrum, excepting the extreme half of the violet, as well as in the ultra-red. A continuous increase in the loudness of the sound was observed upon moving the receiver gradually from the violet into the ultra-red. The point of maximum sound lay very far out in the ultra-red. Beyond this point the sound began to decrease, and then stopped so suddenly that a very slight motion of the receiver made all the difference between almost maximum sound and complete silence.

2. The lamp-blacked wire gauze was then removed and the interior of the receiver was filled with red worsted. Upon exploring the spectrum as before, entirely different results were obtained. The maximum effect was produced in the green at that part where the red worsted appeared to be black. On either side of this point the sound gradually died away, becoming inaudible on the one side in the middle of the indigo, and on the other at a short distance outside the edge of the red.

3. Upon substituting green silk for red worsted the limits of audition appeared to be the middle of the blue and a point a short distance out in the ultra-red. Maximum in the red.

4. Some hard-rubber shavings were now placed in the receiver. The limits of audibility appeared to be on the one hand the junction of the green and blue, and on the other the outside edge of the red. Maximum in the yellow. Mr. Tainter thought he could hear a little way into the ultra-red, and to his ear the maximum was about the junction of the red and orange.

5. A test-tube containing the vapour of sulphuric ether was then substituted for the receiver. Commencing at the violet end, the test-tube was gradually moved down the spectrum and out into the ultra-red without audible effect, but when a certain point far out in the ultra-red was reached a distinct musical tone suddenly made its appearance, which disappeared as suddenly on moving the test-tube a very little further on.

6. Upon exploring the spectrum with a test-tube containing the vapour of iodine the limits of audibility appeared to be the middle of the red and the junction of the blue and indigo. Maximum in the green.

7. A test-tube containing peroxide of nitrogen was substituted for that containing iodine. Distinct sounds were obtained in all parts of the visible spectrum, but no sounds were observed in the ultra-red.

The maximum effect seemed to me to be in the blue. The sounds were well-marked in all parts of the violet, and I even fancied that the audible effect extended a little way into the ultra-violet, but of this I cannot be certain. Upon examining the absorption-spectrum of peroxide of nitrogen it was at once observed that the maximum sound was produced in that part of the spectrum where the greatest number of absorption lines made their appearance.

8. The spectrum was now explored by a selenium cell, and the audible effects were observed by means of a telephone in the same galvanic circuit with the cell. The maximum effect was produced in the red. The audible effect extended a little way into the ultra-red on the one hand and up as high as the middle of the violet on the other.

Although the experiments so far made can only be considered as preliminary to others of a more refined nature, I think we are warranted in concluding that the nature of the rays that produce sonorous effects in different substances depends upon the nature of the substances that are exposed to the beam, and that the sounds are in every case due to those rays of the spectrum that are absorbed by the body.

Our experiments upon the range of audibility of different substances in the spectrum have led us to the construction of a new instrument for use in spectrum analysis. The eye-piece of a spectroscope is removed, and sensitive substances are placed in the focal point of the instrument behind an opaque diaphragm containing a slit. These substances are put in communication with the ear by means of a hearing-tube, and thus the instrument is converted into a veritable "spectrophone."

Suppose we smoke the interior of our spectrophonic receiver, and fill the cavity with peroxide of nitrogen gas. We have then a combination that gives us good sounds in all parts of the spectrum (visible and invisible) except the ultra violet. Now pass a rapidly-interrupted beam of light through some substance whose absorption spectrum is to be investigated, and bands of sound and silence are observed upon exploring the spectrum, the silent positions corresponding to the absorption bands. Of course the ear cannot for one moment compete with the eye in the examination of the visible part of the spectrum; but in the invisible part beyond the red, where the eye is useless, the ear is invaluable. In working in this region of the spectrum lamp-black alone may be used in the spectrophonic receiver. Indeed the sounds produced by this substance in the ultra-red are so well marked as to constitute our instrument a most reliable and convenient substitute for the thermo-pile. A few experiments that have been made may be interesting.

1. The interrupted beam was filtered through a saturated solution of alum.

Result: The range of audibility in the ultra-red was slightly reduced by the absorption of a narrow band of the rays of lowest refrangibility. The sounds in the visible part of the spectrum seemed to be unaffected.

2. A thin sheet of hard rubber was interposed in the path of the beam.

Result: Well-marked sounds in every part of the ultra-red. No sounds in the visible part of the spectrum, excepting the extreme half of the red.

These experiments reveal the cause of the curious fact alluded to in my paper read before the American Association last August—that sounds were heard from selenium when the beam was filtered through both hard rubber and alum at the same time.

3. A solution of ammonia-sulphate of copper was tried.

Result: When placed in the path of the beam the spectrum disappeared, with the exception of the blue and violet end. To the eye the spectrum was thus reduced to a single broad band of blue-violet light. To the ear however the spectrum revealed itself as two bands of sound with a broad space of silence between. The invisible rays transmitted constituted a narrow band just outside the red.

I think I have said enough to convince you of the value of this new method of examination, but I do not wish you to understand that we look upon our results as by any means complete. It is often more interesting to observe the first totterings of a child than to watch the firm tread of a full-grown man, and I feel that our first footsteps in this new field of science may have more of interest to you than the fuller results of mature research. This must be my excuse for having dwelt so long upon the details of incomplete experiments.

I recognise the fact that the spectrophone must ever remain a mere adjunct to the spectroscope, but I anticipate that it has a wide and independent field of usefulness in the investigation of absorption spectra in the ultra-red.

ON AN ACOUSTIC PHENOMENON NOTICED IN A CROOKES TUBE [1]

A SHORT time since, while experimenting with a Crookes tube, I noticed a phenomenon which was quite striking, and so evident that it hardly seems possible that it has not frequently been observed before; but as no allusion to the effect in question has come to my notice, I venture to call attention to it.

In working with the tube in which a piece of sheet platinum is rendered incandescent by the concentration upon it of electrified particles, repelled from a concave mirror, I noticed that when the mirror was made the negative electrode, so that this concentration took place, a clear and quite musical note issued from the tube. I thought at first that the pitch of the note would coincide with that produced by the circuit-breaker used with the coil (which made about 100 breaks per second), but this did not prove to be the case. In fact very great changes in the rate of the circuit-breaker did not affect the note given by the tube. The effect seemed to be produced by the vibration of the sheet-platinum in its own period, under the influence of the molecular impact, which vibration was communicated to the glass walls of the tube by the enamel rod to which the platinum was attached, giving rise to a sound somewhat resembling the pattering of rain against a window-pane, but higher in pitch and more musical. This sound changed its character very greatly when the direction of the current was reversed, a feeble murmur only being heard. I obtained a similar musical note, though far less loud, with the "mean free-path tube," best when the middle plate was positive. With a tube containing phosphorescent sulphide of calcium, the note was very dull in its quality and low in pitch, but still quite perceptible. With this tube a change in the direction of the current, as might be expected, did not affect the sound produced. I did not obtain this musical note from any tube that I have in which the current enters and leaves by a straight wire, except in the case of a single Geissler's tube exhausted so as to give stratifications, in which it was very feebly heard.

[1] Read by C. R. Cross at a meeting of the American Academy of Arts and Sciences, November 10, 1880.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

A LARGE number of ladies and gentlemen assembled on Tuesday in Cowper Street to witness the laying of the foundation-stone of the Finsbury Technical College which it has lately been resolved to establish by the City and Guilds of London Institute, by His Royal Highness Prince Leopold. According to the report of the Council of the Institute to the Governors, the projected building is estimated to cost 20,382*l.*, exclusive of the professional charges, fittings, and other incidental expenses, which will amount to some 5000*l.* In the plans ample accommodation is provided for instruction in the application of physics, chemistry, and mechanics to the various industries. The building will contain thirty-two rooms, including a large laboratory, two lecture theatres, class, drawing, private, and engine rooms, workshops, and clerks' offices. Lord Selborne, in welcoming the Prince, after noting the progress of science as applied to arts and manufactures in this and other countries, said that in the race of competition the prize must in the end belong to those who best knew how to build the superstructure of arts and manufacture on their handicrafts with a sound foundation of scientific knowledge. The ceremony of laying the stone was gone through by Prince Leopold, who in the course of his remarks said that the institution has proclaimed its determination to enter into generous rivalry with other countries in those branches of trade and commerce in which, one must needs confess, our native industries have of late years not taken that position which we as Englishmen would wish them to occupy. We are beginning to realise that a thorough and liberal system of education must be placed within the reach of the British artisan in order to enable him to hold his own against foreign competition. Mr. Mundella said that by instituting this college they were taking the same step in applying science to industries which had been taken in applying arts to manufactures at South Kensington. Among the articles deposited in the cavity of the foundation-stone was a copy of NATURE.

THE Berlin correspondent of the *Times* states that a movement is afoot among the Germans in the United States for the creation of a native University on the model of those in the old country, to be called the Kaiser Wilhelm Universität, in commemoration of the "glorious resuscitation of the Fatherland." Milwaukee is mentioned as the likeliest candidate among all the cities of the West that aspire to the honour of harbouring this plant of pure Teutonic culture, which would cost, to begin with, about two million dollars. It is not at all probable, however, that the scheme will come to anything.

SCIENTIFIC SERIALS

THE *Journal of Anatomy and Physiology* for April, 1881 (vol. xv. part 3), contains:—On the bones, articulations, and muscles of the rudimentary hind-limb of the Greenland right whale (*Balæna mysticetus*), by Dr. J. Struthers.—On the stridulating apparatus of *Callonystax gagata*, by Prof. A. C. Haddon (Plate 20).—On the sternum as an index of age and sex, by Dr. Thomas Dwight (concludes that the breast-bone is no trustworthy guide either to the sex or the age).—On the mechanism of costal respiration, by Dr. J. M. Hobson (with figures).—On the membrana propria of the mammary gland, by Dr. C. W. M. Moullin (with figures).—On double and treble staining of microscopical specimens, by Dr. W. Stirling.—On the comparative anatomy of the lymphatics of the mammalian urinary bladder, by Drs. George and F. Elizabeth Hoggan (plate 21).—Notes on a dissection of a case of epispadias, and on the morphology of the muscles of the tongue and pharynx, by Dr. R. J. Anderson.—On the so-called movements of pronation and supination in the hind-limb of certain marsupials, by Dr. A. H. Young.—A contribution to the pathological anatomy of pneumonokoniosis (*Chalicosis pulmonum*), by Thos. Harris (plate 22).—On the histology of some of the rarer forms of malignant bone tumours, by Robt. Maguire.—On the morbid histology of the liver in acute yellow atrophy, by Prof. Dreschfeld.—On the relationship between the muscle and its contraction, by Dr. J. Theodore Cash.—Anatomical notes.

The Quarterly Journal of Microscopical Science, April, 1881, contains—On the minute anatomy of the branchiate echinoderms, by P. Herbert Carpenter (plates 11 and 12).—On young stages of Limnocodium and Geryonia (plate 13), and observations and reflections on the appendages and on the nervous system of *Apus cancriformis*, by E. Ray Lankester (plate 20).—On the origin and significance of the metamorphosis of Actinotrocha, by Edmund B. Wilson (plates 14 and 15).—A further contribution to the minute anatomy of the organ of Jacobson in the guinea-pig (plates 16 and 17), and histological notes, by Dr. E. Klein.—On the development of microscopic organisms occurring in the intestinal canal, by Dr. D. Cunningham (plate 18).—Researches upon the development of starch-grains, by A. F. W. Schimper (plate 19), translated from the *Botanische Zeitung*.—On the cause of the striation of voluntary muscular tissue, by Dr. J. B. Haycraft.—On the relation of micro-organisms to disease, by Prof. Lister; with notes and memoranda.

The American Naturalist, April, 1881.—Wm. Trelease, on the fertilisation of *Salvia splendens* by birds. (The fertilisation is apparently effected by a humming-bird.)—Prof. E. D. Cope, on the origin of the foot-structures of the Ungulates.—C. A. White, progress of invertebrate palæontology in the United States for 1880.—Carl F. Gissler, evidences of the effect of chemico-physical influences on the evolution of branchiopod Crustaceans.—Dr. R. W. Schufeldt, notes on a few of the diseases and injuries of birds.—A. S. Packard, jun., the brain of the locust (with three plates).

Bulletin of the United States Geological and Geographical Survey of the Territories, vol. vi. No. 1.—On the vegetation of the Rocky Mountain region and a comparison with that of other parts of the world, by Asa Gray and Joseph D. Hooker (pp. 1, 77).—On some new Batrachia and Reptilia from the Permian beds of Texas; on a wading bird from the Amyzon shales; on the Nimravidæ and Canidæ of the Miocene period; and on the Vertebrata of the Wind River Eocene beds of Wyoming, by E. D. Cope.—The osteology of *Speotyto cunicularia*, var. *hypogæa*, and on the osteology of *Eremophila alpestris*, by Dr. R. W. Schufeldt.—A preliminary list of the North American species of Agrotis, by A. R. Grote.

Revue internationale des Sciences biologiques, March, 1881.—Prof. Strasburger, the history of the actual state of the cell theory.—M. Debierre, physical and biological dynamism.—Prof. Ray Lankester, embryology and classification of animals.

Brain: a Journal of Neurology.—Part 13 for April, 1881, contains, of original articles:—Dr. J. C. Bucknill, on the late Lord Chief Justice (Sir A. Cockburn) of England.—Dr. B. Bramwell, on the differential diagnosis of paralysis.—Dr. A. Flint, jun., on the cause of the movements of ordinary respiration.—Dr. Julius Althaus, on some points in the diagnosis and treatment of brain disease.—Dr. C. S. W. Cobbold, observations on certain optical illusions of motion.—Bevan Lewis, methods of preparing, demonstrating, and examining cerebral structure in health and disease.

Revue des Sciences Naturelles, 2me série, tome 2, No. 4, March, 1881, contains:—M. A. Salvatier, on the mechanism of respiration in the Chelonians (plates 5 and 6).—Dr. E. Jourdan, notes on the anatomy of *Distomum clavatum*, Rud (plates 7 and 8).—M. A. Villot, another word on the fresh-water Pliocene of the Bas Dauphiné.—M. Collot, provisional study of the Anthracotherium remains from the lignites of Volx.—M. Viguier, note on the lithographic chalks of Nebias.—M. Kieffer, on the herborisations of Strobelberger at Montpellier in 1620 (*finis*).—Scientific review of works published in France on zoology, botany, and geology.

Journal of the Asiatic Society of Bengal, 1880, No. 4 (vol. xlix. Part 2).—W. T. Blanford, contributions to Indian Malacology, No. 12—new land and fresh-water shells from Southern and Western India, Burmah, the Andamans, &c. (plates 2 and 3).—J. Wood Mason and L. de Nicéville, diurnal Lepidoptera from Port Blair, with descriptions of some new or little-known species, and of a new species of Hestia from Burmah (plate 13).—W. T. Blanford, description of an Arvicola (*A. Wynnei*) from the Punjab Himalaya.—Capt. G. F. L. Marshall and L. de Nicéville, new species of Rhopalocerous Lepidoptera from the Indian region.—J. Wood Mason, Parantirrhœa Marshalli, the type of a new genus and species of Rhopalocerous Lepidoptera from South India.

Verhandlungen der k. k. zoologisch-botanischen Gesellschaft in Wien, Bd. xxx., Heft 2, 1881, contains the minutes of proceedings, June to December, 1880, and the following memoirs:—F. Krasan, report in connection with new investigations on the development and origin of the lower organisms (plate 7).—Dr. A. v. Krempelhuber, a new contribution to the lichen flora of Australia.—Th. Beling, the metamorphosis of *Cænomyia ferruginea*, Scop.—Prof. Josef Mik, on the mounting and collecting of Diptera, descriptions of new Diptera, and dipterological notes (plate 17).—H. B. Moschler, contribution to the Lepidoterous fauna of Surinam, No. iii. (plates 8 and 9).—S. Schulzer, mycological contributions.—J. Stussiner, *Leptomastax Simonis*, a new species of subterranean beetle.—Hans Leder, on the Coleopterous fauna of the Caucasus, No. iii., in co-operation with Dr. Eppelsheim and E. Reitter.—D. Hire, the Molluscan fauna of the Liburnian Karst.—Fritz Wachtl, contribution to our knowledge of the European gall-producing insects (plate 18).—Count E. Keyserling, new American spiders (plate 16).—Dr. Ludwig Lorenz, on *Distomum robustum*, sp. n., from the African elephant (plate 19).—A. von Pelzeln, on a hornless deer.—Dr. F. Löw, on a more exact knowledge of the procreativeness of the sexual individuals in Pemphigus.—Dr. R. Drasche, on a new species of Echiurus from Japan (*E. unicinctus*), and remarks on *Thalessema erythrogrammon*, Leuckart (plate 20).—Dr. R. Bergh, monograph of Polyceridæ (plates 10 to 15).

Gegenbaur's morphologisches Jahrbuch, vol. 17, part 1, contains—Prof. Oscar Herburg, on the exoskeleton of fishes: No. 3, the Pediculati, the Discoboli, the genus Diana, the Centriscidæ, some genera of Triglidæ, and the Plectognathi (plates 1 to 4).—On the duplex nature of the ciliary ganglion, by Prof. W. Krause (plate 5).—On the abdominal muscles of the crocodiles, lizards, and tortoises, by Dr. Hans Gadow (plate 6).—Contributions to the developmental history of Petromyzon, by W. B. Scott (Princeton), (with plates 7 to 11).—On the "pars facialis" of the lachrymal bone, by Prof. Gegenbaur.

Rivista Scientifico-Industriale, No. 6, March 31.—On earthquakes, by Dr. Bassani.—New plant, by S. Fenzi.—Determination of the velocity of sound in chlorine, by Prof. Martini.

Sitzungsberichte der naturforschenden Gesellschaft zu Leipzig, 1879-80.—On double monstrosities in fishes, by Prof. Rauber.—On the finer structure of milk-glands, by the same.—On Aphthæ, by Prof Hennig.—On results of glacier thrust, by Prof. Credner.—On the geological results of a deep boring at the Berlin Railway at Leipzig, by the same.—On the reduction of anatomical forms to equal size, by Prof. Hennig.—On the system of spinal ganglia, by Prof. Rauber.—On chlorophyll, by Dr. Sachsse.—On an optical combination which may be applied as objective of a telescope, by Dr. von Zahn.—On *Lichen bombicinus*, by Prof. Hennig.—On the development of cells to organs of locomotion, by Dr. Simmroth.—On Negrito skeletons from the Philippines in European museums, by Herr Meyer.—On the cycle of forms of some unicellular algæ, by Herr Richter.

Atti della R. Accademia dei Lincei, vol. v. fasc. ix.—On the discharge of condensers, the theory of the electrophorus, and its analogy with condensers, by Prof. Villari.—New observations of Pechüle's comet at the Royal Observatory of the Roman College, by P. Tacchini.—Two solar regions in continuous activity during 1880, by the same.—On the motion of a heterogeneous fluid ellipsoid, by S. Betti.—New method for the volumetric evaluation of molybdenum, by Signors Mauro and Dunesi.—On some compounds of the furfuric series, by Signors Ciamician and Dennstedt.—Separation and determination of nitric and nitrous acid, by S. Piccini.—Observations on the method commonly adopted in treatment of like fundamental questions of infinitesimal analysis, by S. Casorati.—On the drainage works of the Roman subsoil, by S. Tommasi Crudeli.

SOCIETIES AND ACADEMIES

LONDON

Zoological Society, May 3.—Prof. W. H. Flower, LL.D., F.R.S., president, in the chair.—Prof. F. Jeffrey Bell, F.Z.S., read the first of a series of papers on the systematic arrangement of the *Asteroidea*. In the present communication the author directed attention to the large number—more than eighty—of described species of the genus *Asterias*, the subdivision of which had never yet been attempted. After a list of the species with reference to one description of each, and a list of the synonyms, he proceeded to describe and make use of certain characters as an aid in the classification of the species; the number of rays, of madreporiform plates, and of ambulacral spines forming the more important, and the form and character of the spines the less important points. The author then proposed a mode of formulating results by the use of certain symbols, and concluded by describing five new species.—A communication was read from Dr. M. Watson, F.Z.S., containing some observations on the anatomy of the generative organs of the spotted hyæna, in continuation of a previous paper on the same subject.—Mr. Oldfield Thomas, F.Z.S., read a memoir on the Indian species of the genus *Mus*. The present paper was an attempt to clear up the existing confusion in the synonymy of the Indian species of this genus, of which the author recognised about nineteen as valid.—A communication was read from Mr. Edgar A. Smith, containing remarks on some specimens of *Cyprææ decipiens*, lately received by the British Museum.—A second paper by Mr. Smith contained the description of two new species of shells from Lake Tanganyika.—Capt. G. E. Shelley read a paper containing an account of seven collections of birds recently made by Dr. Kirk in the little explored regions of Eastern Africa. Two new species were proposed to be called *Coccystes alboniotatus* and *Urobrachya Zanzibarica*.—Mr. Arthur G. Butler, F.Z.S., read a paper on a collection of Lepidoptera made in Western India, Beloochistan, and Afghanistan by Major Charles Swinhoe. The collection contained examples belonging to three new genera and fifteen new species.

Chemical Society, May 5.—Dr. Roscoe, president, in the chair.—The following papers were read:—On the action of humic acid on atmospheric nitrogen, by E. W. Prevost. The author has repeated some of the experiments of E. Simon (*Lana. Vers. Stats*, xviii.) on the above action; he is quite unable to confirm the results of that investigator, and concludes that under ordinary circumstances no formation of ammonia takes place when humic acid and nitrogen are allowed to remain in contact.—On the active and inactive amylamines corresponding to the active and inactive alcohols of fermentation, by R. T. Plimpton. The author has prepared and examined the mono-, di-, and triamylamines and some of their compounds. The active amylamines polarise strongly; their salts do not crystallise

so well as those of the inactive amylamines; there is also some difference in the boiling-points and specific gravities of these two classes of bodies.—On the action of sodium alcoholates on fumaric ethers, by T. Purdie. An acid is formed which is an ethylethermalic acid isomeric with the monethylmalate of Desmondisir. The action of sodium isobutylate on isobutyl fumarate was also studied; an isobutylmalic acid was formed.—On the products of the action of alkalies on ethylic β ethylacetosuccinate, by L. T. Thorne. An ethylsuccinic acid was obtained by the action of strong potash identical with that obtained from the α succinate; with weak potash 5 per cent. α-ethyl-β-aceto-propionic acid was obtained, which on boiling gave off water and formed a body $C_7H_{10}O_2$.—On some carbazol compounds, by C. H. Rennie and W. R. Hodgkinson. The authors have studied the action of potassium carbazol on ethyl chlorocarbonate; a new urethane was obtained.

Geological Society, April 27.—R. Etheridge, F.R.S., president, in the chair.—Samuel Gerrard Kirchhoffer, Arthur Henry Shakspere Lucas, and Lieut. Frederick Thomas Nelson Spratt were elected Fellows of the Society. The following communications were read:—On the precise mode of accumulation and derivation of the Moel Tryfan shelly deposits; on the discovery of similar high-level deposits along the eastern slopes of the Welsh mountains; and on the existence of drift-zones showing probable variations in the rate of submergence, by D. Mackintosh, F.G.S.—On the correlation of the Upper Jurassic rocks of England with those of the Continent, by the Rev. J. F. Blake, M.A., F.G.S. Part I. the Paris basin. This was an attempt to settle the many questions of correlation arising out of the detailed descriptions given of the various localities in the Paris basin where Upper Jurassic rocks are developed, by a consecutive survey of them all; undertaken by the aid of a grant from the "Government Fund for Scientific Research." In previous papers the names used for the great sub-divisions and their boundaries were adopted without material modification; in the present such modifications were proposed as may bring the English and Continental arrangements into harmony. Five distinct areas were considered in this paper:—(1) The southern range; (2) the Charentes; (3) Normandy; (4) the Pays de Bray; (5) the Boulonnais. From this study it was proposed—that the "Lower Calcareous grit" and almost all the Coralline oolite should be placed in the Oxfordian series as the upper division, under the name "Oxford Grit" and "Oxford Oolite"; that the Corallian consists of two parts, the Coral Rag and the Supra-coralline beds; that the Kimmeridgian should include the Astartian and Virgulian, the Pterocerian being a subzone; that the "Upper Kimmeridge" and the Hartwell clay, with the "Portland sand," should make a new sub-division to be called Bolonian, the northern and southern types being both represented at Boulogne, which may be divided into upper and lower; and that the true Portland limestone and the Purbeck be united into one group, as Lower and Upper Portlandian; the fact of the latter being freshwater being paralleled by parts of the true Portland having that character.—On fossil chilostomatous Bryozoa from the Yarra-Yarra, Victoria, Australia, by Arthur William Waters, F.G.S.

Anthropological Institute, April 26.—Prof. W. H. Flower, F.R.S., vice-president, in the chair.—Mr. J. E. Price exhibited a collection of bones of man and other animals discovered by himself and Mr. Hilton Price at the Roman villa at Brading, Isle of Wight. The bones had been examined by Prof Flower, who reported that they were all in much the same state of preservation, and probably all contemporaneous. They consisted of (1) Man: fragments probably of one and the same skeleton. From the condition of the bones it is certain that the individual was adult and probably of middle age and about the average stature. (2) Dog: Numerous remains of at least three individuals, all of nearly the same age and size, not more than half-grown, having only the milk teeth in place. (3) Ox: Young. (4) Horse: One incisor tooth.—Mr. A. L. Lewis read a paper on some archaic structures in Somersetshire and Dorsetshire. The author, in speaking of the great stone circles at Stanton Drew, near Bristol, mentioned the elaborate astronomical theories which had been propounded concerning them by antiquaries of the last century, and said that, while he had no belief in them, he thought that the larger stone circles, of which this group was a specimen, had been used as places for solar worship; there was in nearly all of them some special reference to the north-east, the quarter in which the sun rose on the longest day; in some, however, there were outlying stones towards the south, and this was the case at a circle at Gorwell in Dorsetshire; these stones, whether to the south or the north-east, were evidently so placed for some special object, as the number of instances in which they occurred was too great for their position to be merely accidental. The paper was illustrated by the exhibition of plan, model, and some worked flints, &c., found by the author at some of the monuments mentioned by him.—Mr. G. M. Atkinson read a paper on a new instrument for determining the facial angle. A needle is inserted into each optic foramen, and fixed at a point in the centre of each orbit; the needles are connected by an axle with flat ends which slide on the needles; an index-pointer is attached to the axle in the middle, and is in the same visual horizontal plane as the needles. A bar, carrying a semi-circular protractor, is constructed to be affixed at the centre-point of the protractor, and to have free movement in a vertical plane alongside the index-pointer. If this bar-protractor be placed in position on the skull so as to touch the ophryon and alveolar points, the number of degrees in the facial angle, by this method, will be indicated by the index-pointer on the protractor.—The Rev. W. S. Caiger read a paper on Thomas of Aquinum and anthropology.

Royal Microscopical Society, April 13.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—A paper by Mr. W. H. Shrubsole and Mr. F. Kitton, on the diatoms discovered by the former in the London clay, was read. Also one by Dr. Anthony, on sliding stage diaphragms.—The other subjects discussed were E. Hallier's view of the cause of the movements of diatoms, the "Society" standard screw, *Amphipleura pellucida* illuminated by the vertical illuminator, and the structure of wood-sections exhibited by Mr. Stewart.—Mr. Powell exhibited an oil-immersion ⅛-inch objective of the exceptionally large aperture of 1·47 N.A. (1·0 = 180° in air).

Edinburgh

Royal Society, April 17.—Sir William Thomson, honorary vice-president, in the chair.—Prof. Helmholtz, in an interesting communication on electrolytic conduction, stated that the experiments he was about to describe were a continuation of experiments he had formerly made in connection with certain objections that had been urged against Faraday's law of electrolysis. He had already shown that a feeble galvanic current could be passed through an electrolytic preparation of acidulated water, even though the electromotive force was not sufficient to decompose the water. The action of such a current would be, in the first place, to coat the electrodes, the one with hydrogen, the other with oxygen. The hydrogen however speedily combined with the free oxygen in the air and liquid to form water, while the oxygen on the positive electrode as speedily dissipated itself. In this way the polarisation in the electrolytic cell was kept down, so that the original current was never wholly destroyed. In the later experiments Prof. Helmholtz had completely removed the air from the neighbourhood of the electrolyte. This was effected by an ingenious use of the property possessed by palladium of holding large quantities of hydrogen gas in its pores. With this specially-prepared cell he found that a feeble current passed through it fell down to zero in a very short time, the difference of potential due to the polarisation of the electrodes quite balancing the original electromotive force. On throwing off the battery the polarised electrolytic cell showed on a delicate galvanometer a reversed current, which rapidly fell to zero from an intensity equal to that of the original current before polarisation set in. Another result to which his researches had led him was that there were no *chemical* forces acting between the molecules of an electrolyte other than those that existed in virtue of what might be called their electric charges—a result which cannot fail to have an important bearing upon the question of chemical constitution.—Sir William Thomson communicated a short paper on the average pressure due to impulse of vortex-rings on a solid. When a vortex-ring is approaching a plane large in comparison to the dimensions of the ring, the total pressure over the surface is *nil*. When a ring approaches such a surface it begins to expand, so that if we consider a finite portion of the surface the total pressure upon it due to the ring will have a finite value when the ring is close enough. In a closed cylinder any vortex-ring approaching the plane end will expand out along the surface, losing in speed as it so does, until it reaches the cylindrical boundary, along which it will crawl back, on rebounding, to the other end of the cylinder. As it approaches, it will therefore exert upon the plane surface a definite outward pressure, whose time-integral is equal to the original momentum of the vortex, and

a precisely equal pressure as it leaves the surface. Hence, in the case of myriads of vortex-rings bombarding such a plane surface, though no individual vortex-ring leaves the surface immediately after collision, for every vortex-ring that gets entangled in the condensed layer of drawn-out vortex-rings another will get free, so that in the statistics of vortex-impacts the pressure exerted by a gas composed of vortex-atoms is exactly the same as is given by the ordinary kinetic theory, which regards the atoms as hard elastic particles.—Prof. Tait, in a brief paper on the crushing of glass by pressure, indicated certain results he had obtained by experiments, which were in good accord with the mathematical theory of the strains to which a closed cylindrical glass tube under high pressure is subjected. Of the three stresses, radial, tangential, and longitudinal, which may be regarded as acting upon any elementary portion of the wall of the tube, the two former have a *shearing* effect, to which the crushing of the tube is due. From the few experiments that had been completed it appeared that the shear required to disintegrate ordinary lead glass was about $1 \pm \frac{1}{10}$.—Prof. J. Blyth gave an account of experiments which he had made on the cause of the sounds produced in the microphone receiver. He also exhibited another form of telephone, in which the vibrating membrane was attached rigidly to a copper wire dipping into a column of mercury which formed along with the wire part of the circuit. The inductive effect of the current on itself caused the wire and the attached membrane to vibrate in exact correspondence with the variations of the current.

PARIS

Academy of Sciences, May 2.—M. Wurtz in the chair.—The following papers were read:—Note on a property of the indicatrix, relative to the mean curvature of convex surfaces, by M. Faye.—On the inverse electromotive force of the voltaic arc, by M. Jamin. With a continuous battery current this inverse force presents a resistance to be first overcome; but with alternately contrary currents from a magneto-machine renewed at least 500 times per second, the current at each inversion profits momentarily by the inverse force called forth during the previous emission. Hence the possibility of lighting several arcs in the same circuit of a machine (and the number increases rapidly with the velocity).—Formation of a marine zoological station in the Eastern Pyrenees, by M. de Lacaze-Duthiers. Some proposed harbour alterations at Port Vendres led the author to look about for another suitable locality. Banyuls-sur-Mer made prompt application, with generous offers of help in the case of being chosen. The Port Vendres authorities were also urgent. At Perpignan the project was cordially received. Thus promises have been made of a capital of 32,000 francs, an annual sum of 750 francs, a site, a boat, and the product of a subscription. The President expressed the satisfaction of the Academy.—The derangements of progression, of station, and of equilibration arising in experiments on the semicircular canals or in maladies of these canals, are not the effects of these, but of the influence they have on the cerebellum; note by M. Bouillaud.—On the inequalities with long periods in the movements of heavenly bodies, by M. Gyldén.—On the stratigraphic series of rocks which form the ground in Upper Auvergne, by M. Fouqué. Apart from unimportant flows of Miocene basalt the series of volcanic rocks there comprises two distinct periods, both commencing with strong projections and eruptions of trachytic and acid Andesitic rocks, and terminating with very basic eruptions, porphyroid basalt and basalt of plateaux.—Examination of some artificial products obtained by James Hall, by MM. Fouqué and Lévy. Living in the end of last century, he seems to have been the first who artificially reproduced an eruptive crystalline rock (viz., whinstone).—On salicylic acid and its applications, by M. Schlumberger. *Inter alia*, it has been given daily to animals in some places for years as a protective against contagious disease. To preserve beer it is introduced twice, the first dose being only sufficient to act on lactic ferments, not yeast; a second dose prevents the alcoholic degenerating into acetic fermentation. The two doses together amount to not more than $\frac{1}{2000}$ or 0·05 gr. per litre. It is estimated that 5,000,000 hectolitres of wine were salicylised in France in 1880.—Observations of the comet *f* 1880 (Pechüle) at Paris Observatory, by M. Bigourdan.—On the principle of conservation of electricity, or second principle of the theory of electric phenomena, by M. Lippmann. The algebraic sum of all the simultaneous variations of charge is always nil. Hence the sum of the quantities of free electricity is invariable, since its total variation is always equal to zero. This law extends to all the phenomena hitherto studied. M. Lippmann translates it into analytical language.—On the protobromide and protoiodide of chromium, and on the oxalate and protoxide of chromium, by M. Moissan.—On the acetylic derivatives of cellulose, by M. Franchimont.—Action of sulphuric acid on acetic anhydride, by the same.—On a reagent fitted to distinguish ptomaines from vegetable alkaloids, by MM. Brouardel and Boutmy. This reagent is ferricyanide of potassium, which, in presence of pure organic bases produced in the laboratory or extracted from a body after alleged poisoning, is not any way modified, but when brought into contact with ptomaines (cadaveric alkalies) is changed at once to ferrocyanide, and then becomes capable of forming prussian blue with salts of iron.—On a combination of iodoform and strychnine, by M. Lextrait.—On some felspars of the valley of Bagnères-de-Luchon (Haute-Garonne), by M. Filhol.—On the physiological and pharmaco-therapic effects of inhalation of oxygen, by M. Hayem. Inhalation of oxygen is a useful auxiliary to treatment of chlorosis with iron. The action is similar to that of hydrotherapy, which stimulates the nutritive movement and the formation of red corpuscles, without sensibly modifying the individual alterations of these elements. The method effectually suppresses vomiting when not caused by organic lesion of the stomach.—On an approaching scientific voyage to the whale fishery of Vadsö, by M. Pouchet. Vadsö is on the east coast of Finmark. A steam advice-boat, *Le Coligny*, has been placed at M. Pouchet's disposal by Government. The marine fauna and flora and the rocks of the Varanger fiord will be studied, and certain questions in the biology of fishes especially.—Migration of the puceron of the poplar (*Pemphigus bursarius*, Lin.), by M. Lichtenstein.—Trichinæ encysted in the intestinal walls of the pig, by M. Chatin.—Study on some points of the anatomy of *Sternaspis scutata*, by M. Rietsch.—On two meteors observed at Nouvion-en Thierache, by M. Baudrin.

VIENNA

Imperial Academy of Sciences, May 5.—L. Fitzinger in the chair.—The following papers were read:—F. Steindachner, contributions to the knowledge of the river fishes of South America, Part iii.; ichthyological contributions, Part xi., by the same.—Dr. Karl Richter, contributions to a precise knowledge of cell-membranes of the fungi.—Dr. R. Benedikt and v. Hübl, on dinitro- and trinitroresorcin.—K. Fischer, on the salts of resorcinsulphonic acid.—Prof. H. Durège, on bodies (figures) of four dimensions.—A. Brezina, on the meteor-iron of Bolson de Mapimi.—Dr. T. Domac, on hexylene of mannite.—Prof. Stefan, on the evaporation at a circular or elliptical basin.—T. Holetschek, computation of the orbit of the "Peitho" planet (*it* 8), discovered in 1872 by Dr. R. Luther at Düsseldorf.—Dr. H. Seeliger, on the ratio of motion in the asterism of ζ Canci.

THURSDAY, MAY 19, 1881

"A BOOK OF THE BEGINNINGS"

A Book of the Beginnings. By Gerald Massey. Two Vols. (London: Williams and Norgate, 1881.)

IN two large volumes Mr. Gerald Massey has collected together all the principal facts known about Egypt, with a view to trace the origin of mankind. Some portions of his theories are undoubtedly correct, especially those which go to prove that the Egyptians are the oldest known historical race, that they are an African people of a peculiar type, and by no means an Asiatic tribe filtered through the Isthmus of Suez, and in course of time building up a Semitic population in Africa; that evidence of their primitive development is to be found in their physical type; for Mr. Massey is a decided evolutionist, and regards man as evolved from some of the anthropoid apes, especially the black races, whose colour he considers marks their animal descent; that flint and stone weapons, principally of the Neolithic period, have been found in Egypt at different points is undoubted; and that the aboriginal inhabitants of the Nile Valley gradually rose to a higher state of civilisation, and that without a foreign predisposing them, is probably true. When however the author leaves the realms of ethnology and dashes into philology his results are startling, and his deductions so weird and transcendental that they fail to command acquiescence. It is the rash seizing of any word in any dialect which is totally inadmissible, as from such arbitrary selections any absurdity may be perpetrated.

Still more extraordinary is the separation, arbitrary as it appears, of dissyllable words into syllables, and comparing each syllable with any Egyptian one that will give such a meaning as the inquirer wishes. To such proceedings there are no limits, and some of the results are grotesque. The first requirement in the study of a language is to separate the original from the introduced words, and to apply to each a distinct etymology. In all languages nouns are of uncertain origin, verbs and original inflections, affixes and prefixes are more typical. Such derivations, for example, as butter and butterfly from the Egyptian *Put*, "food," and *Ter*, "entire" or "total," and moth from the Egyptian *Mut*, "death," and cooper from the Egyptian *Kheper*, "a bottle," are too far-fetched to entitle them to the designation of philological deductions. But with all this straining at gnats the number of English words, whether original or derivative, which can be tortured into supposed Egyptian origin, is remarkably small. Objecting, as is imperative, to all such vain delusions, it must be admitted that the author has a full right to oppose that system of comparative philology which has been built up from the Sanskrit, the supposed oldest representation of the Aryan languages, to the utter neglect of the older Egyptian, Sumerian, Babylonian, and Chinese. The stately edifice built upon the sand of Sanscritism already shows signs of subsidence, and will ultimately vanish like the baseless fabric of a vision. For by it not the study of the general laws of speech, but only of a comparatively recent development is exhibited. The weakness of the author is however equally manifest here, as he deals with languages which he does not understand, and institutes comparisons on imperfect data, nor does he seem to be aware of the knowledge recently acquired of a prehistoric Chinese. He is however right when he points out that such a Hebrew, not British, name as Adam is more likely to be derived from *Tem* or *Atem*, the Egyptian word for "creator" and "created" being, than the Sanscrit Adima, proposed by Max Müller, the more so that the Pentateuch abounds in Egyptian words, and Sanscrit philology is vainly and ridiculously applied to it. But in treating of the Egyptian word for cat and its vocative form pussy, although the different forms cited may amuse those interested in the "great cat question," the learning expended is not on an original, but an introduced word. The cat was doubtless an African and Chinese animal unknown to the Greeks till a very late period, not introduced till late into the houses of the Romans, and not seen on Egyptian sculptures as a pet till about 1500 B.C. The immense deal of reading and the fanciful comparisons of the section of the Egyptian names of personages are too daring and startling. No doubt there is a peculiar fascination in playing with words, and if the combinations are neither correct nor harmonious, they are at all events amusing, as to find that the Chinese expression *fieng yue* is the same as the word fiend, after all only the Egyptian *fenti*, and "old Bendy," the English nick-name for the devil. The same remarks may also be applied to the attempts to refer British symbolical customs to Egyptian names, and the identification of the Egyptian deities in the British Isles, although a great deal of reading has been wasted. In the wriggling over the word Tasc on British coins, the well-known abridgment of Tasciovanus, the father of Cunobelinus, or Cymbelin, there is an unusual degree of floundering. It is referred to the Egyptian word *tes* and the English *tas*, a reaper, and this example will give an idea of the manner in which the subject is treated. At some spot in Herefordshire certain services were performed over "old Tom"—not the spirit, but as the departed year was called; and this is supposed to be part of the myth or legend of the Egyptian god Atum, or the Creator, Tom in the game of noughts and crosses, and so is Tommy Dodd. The only difficulty is to conceive how such a transformation can have got into any English head, for the word Tom suggests a vulgar familiarity and a contracted form of Thomas; and in the same strain run on the consideration of the types, names, and similar subjects, all on the same plan. From the consideration of Egyptian origins in Britain, a more than doubtful thesis, Mr. Massey however goes into deeper water when he ventures on Egyptian analogies in the Hebrew scriptures, although the subject is by no means novel, and has been mentioned by various Egyptologists, Chabas, De Rouge, Ebers, Brugsch, and others, besides the extensive use of Egyptology made by German theologians. The identification of biblical personages is another of the attempts of the author to grasp at faint analogies with Egyptian words that might possibly be compounded into the Hebrew syllables forming the Hebrew names; the slightest probability is grasped at as if an absolute proof, with the undaunted boldness of a preconceived theory. Such researches may dazzle those unacquainted either with Egyptian or Hebrew, but it is more than doubtful

if such averments will commend themselves either to Egyptologists or Hebraists; they are so transcendental that they do not belong to the domain of pure or comparative philology, but appertain rather to the province of comparative mythology, and the interpretations so liberally accorded of the myths of one nation by the philology of another. They resemble the labours of the school of Bryant, which expended so much learning, obtained such few results, and established no important fact. So with an immense amount of Egyptian reading and learning the real amount of new facts acquired by ingenious comparisons is small, not to say of the most doubtful character. Amongst one of the most startling ideas is that the Arsu, who ruled during the anarchy which preceded the reign of Setnethk or Nekhtset, is no other than Moses. The search for Moses amongst Egyptologists has been most exhaustive, and Prof. Lanth, who also belongs to the imaginative rather than the critical school, has long ago thought that he identified not only the Jewish lawgiver, but all the members of his family, on an Egyptian sepulchral tablet. It is needless to remark that no other Egyptologist recognises in the polytheistic worshipper of Apis the monotheistic leader of Israel.

No doubt many identical verbal roots occur in Egyptian, Assyrian, and Accadian; those of Hebrew and Coptic have already been pointed out and alluded to; still the languages are essentially distinct in their constructions, and belong to different families. The Assyrian may be classed as the oldest form of the Semitic family, at all events the Babylonian must be considered so. Greater difficulty indeed exists about the Accadian, which has been referred with probability by some to the Ugrian family of languages, and with doubtful success by others to the oldest Chinese, as the theory is based on the comparison of few words, some of which are of uncertain meaning, and they cannot be historically traced as the descendants of one another. Some of the Accadian nouns, indeed, resemble the Finnish, but the verbs are totally dissimilar. Many Egyptian words, however, it would appear from the comparative table of Mr. Massey, resemble Accadian, and this may be considered a new departure, and one perfectly legitimate, as the two languages may have started from a common origin; indeed by some linguists the origin of the Semitic has been referred to Africa; but as already clearly pointed out, although certain phases of construction ally the Egyptian with the Semitic languages, there is not the most remote similarity with the Accadian, which is not only of a totally different family from the Semitic, but also the Egyptian or Hamitic tongues. When however Mr. Massey claims to trace Egyptian words in the Maori, he has no doubt been more fascinated by the theory of the Egyptians belonging to a primitive continent subsequently broken into the islands of the Polynesian group than the actual coincidences of the two tongues or the similar words in the two languages. It must always be remembered that, like the Chinese, the Egyptian is a very poor language, and expresses a great variety of ideas by a single monosyllable: no wonder, then, if coincidences occur. The African origin of the Maoris of course demands further consideration. Ethnologically and philologically they were formerly classed as a probable offset of the Malay race, but how Egyptian words passed to them is another question. Some words certainly look like Egyptian; but that is not sufficient, as some Egyptian words resemble those in all other languages.

More in accordance with probability is the hypothesis that Egyptian words may be found in all the African languages, although their structures differ. This has been long recognised as a fact in the Berber, and also in some of the other African stems, but again the great difference of structure and the doubt how and when the Egyptian words were introduced cloud the inquiry in investigating languages that have had no inscriptions or written literature. Yet the old Egyptian must have been a development of one of the old African languages which subsequently became extinct.

Notwithstanding the difference of opinion about the results and the methods by which they have been obtained, great credit is due to Mr. Massey for the ingenuity with which he has endeavoured to build up his theory and, to his mind, discoveries. He has read through all the principal works on the subjects he treats, and his collection of words, legends, and data is enormous. He has produced a work which will be read with pleasure by some, with amazement by others, and incredulity by specialists. He has taken all reasonable care to insure a fair and correct list of words and facts: yet for all that the embroidery of his particoloured threads has produced a weird and grotesque pattern of strange and fantastic conceptions such as might have been planned by elves or fairies to dazzle and bewilder mortal imagination as much as to amuse and delight themselves. It is too warm and rosy for the chill glance of science.

THE SCOTTISH CELTIC REVIEW

The Scottish Celtic Review. No. 1, March, 1881; pp. 80, 8vo. (Glasgow: James Maclehose.)

THIS is a quarterly review of which the first number has just appeared, published by Mr. Maclehose of Glasgow; but the name of the editor is not given, nor of the writers of the articles. The work however is done in a way which shows that there are at least a few persons in the North who feel a deep interest in Celtic philology and the language and literature of the Scotch Highlands. The programme is an excellent one, and embraces among other things the application to the study of Gaelic of those methods of investigation which have been so fruitful in the fields of English and German philology. It is intended also to help, by means of translations, to make English readers better acquainted with Gaelic literature, and to collect for publication all fragments of unwritten literature which still may happen to linger in the Highlands, as well as to afford room for the discussion of questions relating to Gaelic grammar and orthography. This last, it seems to us, is a subject with which the Gaelic scholars of the Highlands trouble themselves a great deal too much. Modern Gaelic orthography, whether in Ireland or in Alban, is simply incorrigible, and had better be left alone for the rest of the natural lives of the surviving dialects. This involves no great inconvenience; for no scholar who wants to understand the history of a Gaelic word ever thinks of being guided by any of the modern spellings which may be in use, but goes back to the Irish of the Middle Ages, or farther still,

to what is technically known as Old Irish. It is some consolation to Englishmen to know that English orthography is not quite the worst in the world, and that Tonald seldom writes, but that when he does he spells more outrageously than the most wayward spelling-book ever known in the land of the Southron.

The philological articles in this review are very well done, and will be found very instructive, and specially adapted for beginners in the study of Celtic; but what we presume would most attract the readers of NATURE in this number is the tale which it contains, published for the first time. It was taken down some years ago in the Island of Tiree, the Terra Ethica of Adamnan's "Life of St. Columba." This is a summary of it:—The King of Ireland's heir was returning from hunting towards the evening, when he was overtaken by a shower, out of which came a big fellow with a fine steed and a marvellously handsome woman. The big fellow challenged the prince to play with him; he did so, and the big fellow was beaten, whereupon the prince took away his lady companion. He met the same big fellow another day and beat him again; according to the woman's advice he asked this time for the steed, which he took away with him home. The woman told him he would be beaten the next time, and how he was to act under his defeat. It happened just as she had told him, the big fellow laying him under charms, that he should have no rest or peace until he discovered how the Tuairisgeul Mor met with his death. He in his turn laid the big fellow under a charm not to leave the spot until he should return from the difficult expedition which was before him, and in which ever so many kings' sons had perished in former times. With the aid of the counsel of the woman he had taken from the big fellow, and with the assistance of her three wonderful brothers, to whom she recommended him, he managed to execute the first part of his business. On his way back on his horse, just as he had ridden through a wide loch and cut it into two, he was met by a youth who made unheard-of offers for the horse; according to previous advice he was to accept none of them, but to give away the horse only for a grey old man the youth had at home. The hero of the tale carries the grey old man on his shoulders and is guided by him, but is always to do the reverse of what he says. Each time this happened the old man would say, "That gives longer life to you and shorter life to me." At last they sat down in a house, and the old man had to relate the tale of his life, which was to yield the prince the information he was in quest of. He said that he was one of the three sons of a king, who were turned into wolves by their stepmother with her mallet of Druidism. They avenged themselves on her by killing her hens, until she got all the sportsmen in the land assembled to destroy them, when they were driven to shelter themselves under a big rock near the sea. There two died, and the surviving one, seeing a ship not far off, swam so near it that the captain ordered him to be picked up. By and by he became a pet of the captain's, who took him home to his wife. Some time afterwards she was confined of a boy, and the midwives, after dressing the baby, went to sleep, while the wolf lay quietly below the bed; ere long he saw a big fist coming in through the roof and snatching the baby away. When the midwives woke they smeared blood on the animal, and laid the blame on it of having devoured the child, in order to clear themselves of neglect. The captain was loath to kill his pet wolf. The same thing happened another year; but the third time the beast watched, and beheld the fist coming in through the roof, when he seized hold of it, and tore it off at the shoulder; however, the other hand seized the child, but the wolf gave chase, and made its way into a little island with a cave in it where he found that the robber was a giant. The baby was under his arm, and the children previously stolen were playing in the cave. The giant being asleep, he got at his throat, and so the Tuairisgeul Mor found his death. After relating how the three children were brought home to their father, the captain, and how he himself recovered his human form, the old man said: "I am not to live any longer; throw me into yonder cauldron." The King of Erin's son now returned to the hill, where the big fellow who used to challenge him to play, lay with his bones by this time bleached by the wind and the rain; but when the prince told him how the Tuairisgeul Mor had been put to death he was gathered together, and rose from the hillock alive and well, while the young prince went home to marry the beautiful maiden who had enabled him to overcome all the difficulties which had met him.

We have read various tales at different times containing similar incidents, but the only one we shall mention here is that of Pwyll, Prince of Dyved, in Lady Charlotte Guest's "Mabinogion," where it is related how he lost his first-born the night he was born; and how another prince of South Wales used to lose the colts of a remarkable mare he had about the same time. At last the latter watched, and cut off the hand that was in the act of seizing a colt through a window; but what we wished to come to was this—the time is specified in the Welsh tale, namely the first day of May every year. Possibly this may suggest to somebody who has made a study of such legends what they really mean; but we abstain from giving any crude theories of our own on the matter.

OUR BOOK SHELF

Zwangsmässige Lichtempfindungen durch Schall und verwandte Erscheinungen auf dem Gebiete der anderen Sinnesempfindungen (Sensations of Light generated by Sound, and related Phenomena in the Sensations of other Organs of Sense). By E. Bleuler and K. Lehmann 8vo, pp. 96. (Leipzig: Fues's Verlag, 1881.)

As the authors (two medical students of Zürich) were conversing on chemistry in the autumn of 1878, Bleuler being asked what was the appearance of *cetones* (substances of which *acetone* or naphtha is the type), got out of the difficulty at once by saying, "They are yellow, because their name contains an *o*." Lehmann, astonished, inquired what such an apparently absurd answer meant, and then found that from childhood Bleuler, on hearing, or even thinking of any vowel or word, immediately saw a colour, and that many of his relatives were in the same condition. Such was the origin of this investigation, and it is remarkable for having been carried on by one who always saw the colours (Bleuler) and one who never saw them (Lehmann). Such appearances of colour generated by sound are here called *photisms*, while sensations of sound generated by colour are termed *phonisms*, and both are called "secondary sensations or perceptions,"

the authors not knowing exactly in which category to place them. The authors have examined 596 persons (383 men and 213 women), and found among them 76 "positive" (that is, capable of seeing photisms), and 520 "negative" (that is, incapable of seeing photisms). This proportion is about 1 to 7. Particulars of the examinations of all are given. The photisms for the same sounds differ much from individual to individual, but remain constant for the same individual, as shown by receiving identical answers to thousands of questions after intervals of more than a year. The photisms are not always distinct or of definite forms, but are projected on to the spot whence the sounds arise. Other senses produce sensations of colour as well as hearing; thus there are taste and smell photisms. There are also emotional photisms. The authors are unable to give any explanation, but they are clear that simple association does not suffice, and they examine a number of suggestions made to them, showing that they do not account for cases observed. They themselves think that the solution of the difficulty is to be sought in the nature of nervous processes, but they do not admit that "secondary sensations" are psychopathological. This little book is full of curious and interesting details evidently connected with Francis Galton's "mental images," and localisation and sometimes colouring of numbers in the mind's eye. The following account of the general conclusions obtained, given on the last page of the book, will show what a curious page of nervous physiology is here opened out.

1. *Bright photisms* are excited by musically high sounds, severe pain, sharply-defined sensations of taste, small forms, pointed forms. *Dark photisms* by the contrary.

2. *Musically high phonisms* are excited by bright light, clear definition, small forms, pointed forms. *Deep phonisms* by the contrary.

3. Photisms with sharply defined forms, small photisms and pointed photisms, are all excited by the sensations of musically high sounds.

4. Red, yellow, and blue are common colours of photisms; violet and green are rare, blue is of medium frequency.

5. Thorough agreement of the separate assertions of different individuals does not occur.

6. Unpleasant primary sensations may excite pleasant secondary sensations, and conversely.

7. Secondary sensations are scarcely more influenced by psychical circumstances than are primary sensations; and they are inalterable.

8. The disposition to have secondary sensations is hereditary.

9. Traces of secondary sensations are widely spread. Well-developed secondary sensations could be established to exist for one in eight persons examined.

10. Secondary sensations are not more frequently met with in psychopathically afflicted persons than in those of a normal condition.

A List of European Birds. By Henry E. Dresser. (London: Published by the Author, 1881.)

THIS "List of European Birds," including all the species found in the Western Palæarctic region, has been very carefully revised by Mr. Dresser, and appears opportunely on the completion of his great work on the "Birds of Europe." It will be most useful as a check list for labelling, or for reference in making exchanges of birds and birds' eggs. The classification is the same as that adopted in the "Birds of Europe," and follows that of Prof. Huxley, which still appears to Mr. Dresser to be the best as yet elaborated. The species are numbered consecutively, in order to facilitate reference. A very few alterations in the nomenclature have been made: 623 species are enumerated, and the list is published at the low price of one shilling.

The Seals and Whales of the British Seas. By Thomas Southwell, F.Z.S. (with Illustrations). (London: Jarrold and Sons, 1881.)

THIS neat little volume, though it adds little if anything to our scientific knowledge of the British seals and whales, will be welcome to many as telling a good deal about these interesting mammals which could only be found after a prolonged search through many of our scientific periodicals. It will form a pleasant addition to sea-side libraries, and, telling what is known about these creatures, it may thus be the means of indicating what is not known about them, and so do something towards advancing knowledge. A good deal of the information in this little volume appeared originally in the pages of *Science Gossip;* it has however not only been carefully revised, but several additional woodcuts have been added. It has also had the supervision of Mr. J. W. Clark and of the late E. R. Alston.

The more advanced student would have liked a short chapter on the literature relating to our British marine mammalia, which perhaps in a future edition might be given, and an analytic key to the species of British cetacea would be a great help to those living in suitable localities who would venture to take up the study of these very interesting but not easily preserved creatures.

A Sequel to the First Six Books of the Elements of Euclid, containing an Easy Introduction to Modern Geometry, with numerous Examples. By John Casey, LL.D., F.R.S. (Dublin University Press Series, 1881.)

THERE are many geometrical results which are not directly formulated or stated in Euclid's Elements, which are yet constantly turning up in the solution of geometrical problems, and it is very desirable to have a handy book of reference, the propositions in which may be cited, so obviating the necessity of a lengthy proof. The "Exercises on Euclid and in Modern Geometry" of Mr. McDowell is a useful book for this purpose, as all the propositions are fully worked out. Dr. Casey, in the course of teaching, has frequently had to contend against the defect above referred to, and had to interrupt the course of the demonstration of an advanced proposition by turning on one side to prove some well-known result, because he could not cite Euclid as an authority for it. This handy little book, which appears to us quite up to the level of the author's reputation as a geometer, is intended to meet this felt want, and paves the way to a deeper study of the modern geometry contained in the exhaustive works by Chasles, Townsend, Mulcaby, and many Continental writers. A great number of classical problems are led up to, and they themselves discussed and established. The size and style of the book fit it for use in the higher forms of our schools, and more advanced students will find it a convenient book for citation.

Accented Four-Figure Logarithms and other Tables for Arithmetical and Trigonometrical Purposes and for Correcting Altitudes and Lunar Distances, with Formulæ and Examples. Arranged and accented by Louis D'A. Jackson. (London: W. H. Allen, 1881.)

MR. JACKSON is an experienced editor and computer of logarithmic tables, having already published "Accented Five-Figure Logarithms," "Pocket Logarithms and other Tables," &c. Different calculations require different degrees of approximations, and the computer learns by experience which kind of tables are best suited for the end he has in view. In his Introduction our author carefully discusses the question, and states to what extent the present tables are efficacious. His system of accentuation appears to be a good one. Certainly it insures a much closer degree of accuracy than is to be got from ordinary four-figure tables. Each logarithm, on its face, shows whether it is in excess or in defect of the true value (obtained by taking a greater number of figures), or equal thereto. The range of error seems to be reduced to a

minimum. The worked-out exercises show that the mode of working is easy of apprehension and leads to correct results. A merit of the book, for frequent use, is that it is handy in form and very clearly printed.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The so-called "Bunsen-Pump"

PROF. ROSCOE, *President* of the Chemical Society of London, in enumerating the works of his friend Prof. Bunsen, says, in NATURE of the 28th ult. ("Scientific Worthies," vol. xxiii. p. 600) :—

"To him we are also indebted for the apparatus for accelerating filtration, the 'Bunsen-pump,' together with all its appliances, now employed in every laboratory."

This assertion requires correction. The pump used by Prof. Bunsen for accelerating filtration was invented by me, and not by Prof. Bunsen, as would appear from the use of his name in connection with it. I described the construction of the "WATER-air-pump" distinctly and plainly in the *Journal* of the Chemical Society of London for January, 1865, under the title, "Researches on the Vacuum : I. The Instruments" (not the instrument, as some will read), and I sent a copy of this paper to Prof. Bunsen, inscribed with a suitable allusion to our former relationship as pupil and teacher, during the spring of 1865. Three years later Prof. Bunsen published his paper, "On the Washing of Precipitates," in which he described again my pump, *but unfortunately omitted to quote my paper of* 1865.

The following is a translation of Prof. Bunsen's own words :—

"To create the difference of pressure for filtration one cannot employ any of the air-pumps commonly used, especially not the mercury-air-pump, as the liquids to be filtered contain not unfrequently chlorine, sulphurous acid, sulphuretted hydrogen, and other substances, which would destroy the metallic portions of the apparatus. I therefore employ a water-air-pump constructed of glass on the principle of Sprengel's mercury-air-pump, which for all chemical purposes is, as I believe, preferable to every other apparatus for air rarefaction, where it suffices to push the rarefaction no further than to a pressure of mercury from 6 to 12 millimetres" (*Ann. Chem. Pharm.*, 1868, vol. cxlviii. p. 277).

The peculiar stress laid here on the uselessness of mercury-air-pumps, and on the fact that chlorine attacks mercury, combined with the omission of all reference to my paper, where both *water and glass* are mentioned, gave to Prof. Bunsen's description of the instrument a colour of originality which Prof. Roscoe (and with him many others) thinks right to support and to perpetuate by calling it the "Bunsen-pump."

As this misnomer has been already the subject of a disclaimer from Prof. Bunsen (NATURE, vol. vii. p. 241), of remonstrances both from myself (vol. vii. p. 241), from Prof. Frankland (vol. xiv. p. 74), and from others, I am sorry to see that Prof. Roscoe should continue to use this designation, which is intended to honour an "*employer*" of the instrument, which hurts the feelings of its inventor and deprives him of his only reward —the satisfaction of being credited with having placed a useful servant at the disposal of science and industry.

If any other inventor less eminent than Prof. Bunsen had made the omission which I have pointed out with much reluctance, no one would persist in giving his name to my child, nor (reversing the case) would anybody speak of a pump as "Sprengel's pump," if I had received from Prof. Bunsen the paper of 1865 and said in 1868, "I therefore employ a water-air-pump constructed of glass on the principle of Bunsen's mercury-air-pump."

H. SPRENGEL

Savile Club, London, May 7

[I have read the foregoing note of expostulation from Dr. Sprengel, and I regret that I have hurt his susceptibilities. That Dr. Sprengel first enunciated the principle both of the water- and of the mercury-air-pump no one can doubt. But that Bunsen devised a water-pump suitable for filtration there can be as little doubt. Hence in speaking of a "filter-pump"—as every chemist knew I was doing—as contradistinguished from an "air-pump," I conceive that I am justified in using the words "Bunsen-pump."—H. E. ROSCOE.]

Tide-Predicting Machines

THE recent discussions respecting tide-predicting machines have called to mind a very old invention of my own, which, although originally designed for a different purpose, seems to me capable of solving the required problems with all attainable accuracy.

I communicated to the British Association at Cambridge in 1845 "A description of a Machine for finding the Numerical roots of Equations and Tracing a variety of useful Curves." An abstract of that paper may be found at pages 3, 4, of the *Transactions* of the sections. About the same time I lithographed for private distribution a more detailed account of the proposed machine, illustrated by diagrams. It begins with the remark that "Persons engaged in testing theory by experiment have frequently derived great assistance from mechanical contrivances, which give rapid and near approximations without the trouble, in every separate case, of going through tedious multiplications and additions. The proposed machine would be capable of giving values of $\Sigma\{b\cos(n\theta + a)\}$, or of tracing the curve $\rho = \Sigma\{b\cos(n\theta + a)\}$."

At page 2 it is shown how it was proposed to trace the curve $\rho = a + b\cos(n\theta + a)$. It is then remarked that, in the same way, it would be possible to trace the curve $\rho = a + b\cos(n\theta + a) + b_1\cos(n_1\theta + a_1) + b_2\cos(n_2\theta + a_2)$, &c. Then follow a variety of suggestions for the practical use of the instrument, and at page 7 there are the following suggestions for the construction of a machine :—

"As toothed wheels cannot be employed to turn the circles (A_1), (A_2), &c., I have made use of a combination of the endless screw and toothed wheels so that the error of the wheels is almost destroyed. H (Fig.) represents a handle attached to an axis on which are mounted toothed wheels $t_1\ t_2\ t_3$ . . . which gear with the wheels $T_1\ T_2$, &c., mounted on separate axes, each having a portion of a very accurate screw. These act on the circumferences of the circles (A_1) (A_2), &c., and cause them to revolve uniformly, as in Ramsden's dividing engine, &c." The large diagram shows four of these (A) circles, each of which gives one term, $b\cos(n\theta + a)$, and these terms are summed by the help of a chain, such as is used to wind up watches, passing over pulleys carried by frames free to oscillate in parallel directions. I inclose copies of the lithographed description of the instrument.

May 9 F. BASHFORTH

Sound of the Aurora

IN NATURE, vol. xxiii. p. 484, one of your correspondents speaks of the sound of the aurora as "crackling," or as that of "the flickering of blazing fire," while another describes it as like the "rustling or switching of silk." On Monday, April 12 last, there was an electric storm here, and at 7 p.m. when I walked home (the blazing lightning leaving but *momentary intervals* of darkness), I heard all round me the constant crackling or rustling of blazing flames. Towards the north-west across a low arc near the horizon pale sheet lightning swayed quickly to and fro. There was no rain at the time, that came heavily afterwards. The sound of flames was close round me, and others had the same experience. No one I can find has ever seen lightning so completely fill the air or heard such strange sounds.

F. C. CONSTABLE

Karachi, April 25

Meteorological Bibliography

I AM compiling a classified bibliography of meteorological science, and being desirous of rendering it as full as possible, I should feel much obliged if you would intimate to meteorologists that by sending copies of their papers to me they would do much towards helping on the work. The publication of this bibliography has already commenced in "The Scientific Roll."

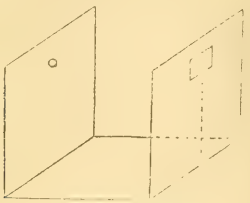
6, Kent Gardens, Ealing, W. A. RAMSAY

An Optical Illusion

THERE is an exquisite optical phenomenon of which I (and doubtless many others too) would be glad to see a really scientific

and physiological explanation. Cannot some one of your numerous scientific contributors favour us with one?

It is this: Take a slip of thin card about three inches long and one wide. Bend up the two end inches at right angles. Perforate one of these vertical ends with a pin-hole, and the other directly and concentrically opposite with a square hole



Observe.—The pin may be placed horizontally, or in any position, with the same result.

about one-eighth of an inch square. Place a small pin in this end, so that the head may be nearly in the middle of the square hole. Now apply this end to your eye and look through both holes at the sky, and you will see the pin apparently beyond the round hole and reversed in position!

WILLIAM WILSON

Eirene, Chester, May 4

[This very pretty experiment seems novel. The explanation is, of course, excessively simple. What is seen is the *shadow* of the pin, thrown on the retina by the light diverging from the small hole. As the shadow is erect on the retina, it produces vision of an inverted pin. This appears to be situated about the distance of most distinct vision (ten inches or so), and therefore behind the hole.—ED.]

LAURENCE HARGRAVE, Sydney, should refer to the letter of the Rev. R. Abbay on the "Rayons de Crépuscule" in vol. xviii. p. 329, and the articles and correspondence therein referred to.

SCIENCE IN CHINA[1]

II.

IT is a generally received opinion that the Chinese language presents extraordinary difficulties, both in its acquisition by Europeans and in its use for the expression of the more exalted ideas of Western learning. The attempt to translate modern scientific or technical books into a language so ancient, so crude, and so unchanging is regarded by many who have not given careful attention to the matter as almost absurd. It is readily granted by them that such subjects as the doctrines of Christianity or affairs of a political nature might be expressed easily in the language of a people among whom religion and diplomacy have for ages been carried to a considerable state of advancement. But from the almost total absence of native scientific literature and pursuits there is necessarily a paucity of scientific terms, and this appears at first sight to form an almost impassable barrier to the use of Chinese for scientific purposes. A little investigation however will show that this opinion is without foundation; and that from the time the early Jesuit missionaries commenced their compilations up to the present day no serious difficulties have been experienced by foreign translators.

The question of nomenclature, however, is one that naturally has to be met at the outset. If it were necessary to use only such terms as are to be found in standard Chinese dictionaries, or if it were forbidden to give any new shades of meaning to existing characters the task of translation could never be accomplished. But it must be borne in mind that the Chinese, like other languages, is capable of growth. The increasing intercourse of China with Western nations is undoubtedly making vast additions to the number of words in current use. The Emperor, it is true, has the power of deciding the exact manner in which characters are to be written, and in various instances certain characters have been forbidden to be written in certain ways; but he is powerless to check the changes and additions that are now fast taking place in the language all over the Empire. Where it has become necessary to express a new idea, or to give a name to a new object in Chinese, there has always been found a way of managing the matter more or less satisfactorily; and hence some very clumsy specimens of nomenclature are gradually becoming current, especially among such natives as have much intercourse with foreigners. Of course all such new terms have to stand or fall on their own merits, and if radically wrong or misleading they are pretty certain eventually to be supplanted by better ones. This is merely what naturally happens in the growth of all languages, and although many inconveniences necessarily occur when terms have to be changed, yet there seems to be no help for it. It will be remembered that when the English language began to borrow largely from Greek and Latin, many scientific and technical terms were coined which have since fallen into disuse or been supplanted by others. So it must necessarily be in Chinese with regard to the words borrowed from the English or other languages.

It ought, however, to be possible for the pioneers of modern sciences and arts in China, by exercising great care and by working in harmony, to establish such a system of nomenclature that no very extensive alterations need be made in future years. A Chinaman of ordinary intelligence ought to be able to take up the translation of a work on such a subject as chemistry, for instance, and understand the nomenclature quite as well as a European of similar capacity, and, knowing nothing of chemistry, would understand the original when placed in his hands for the first time. Every new term being explained or defined only when first used, it would of course be useless for an ordinary Chinaman to begin in the middle of such a work and expect to understand everything he read. And yet not only Chinese but foreigners have been known to treat the translations published at the Arsenal in this way. Finding the nomenclature unintelligible to themselves or their Chinese friends, or their teachers or writers, they have condemned all such attempts to express the higher branches of Western learning in Chinese as useless, and have come to the conclusion that the study of European languages is the only way in which satisfactory progress will ever be made in China.

Before commencing the work of the Translation Department it was seen to be necessary to establish a system by which the nomenclature to be employed should be determined. After considerable discussion the following plan was agreed upon by those who organised the department:—

1. *Existing Nomenclature.*—Where it is probable a term exists in Chinese, though not to be found in dictionaries—

a. To search in the principal native works on the arts and sciences, as well as those by the Jesuit missionaries and recent Protestant missionaries;

b. To inquire of such Chinese merchants, manufacturers, mechanics, &c., &c., as would be likely to have the term in current use.

2. *Coining of New Terms.*—Where it becomes necessary to invent a new term, there is a choice of three methods:—

a. Make a new character, the sound of which can easily be known from the phonetic portion, or use an existing but uncommon character giving it a new meaning.

b. Invent a descriptive term, using as few characters as possible.

c. Phoneticise the foreign term, using the sounds of the

[1] By Mr. John Fryer, Chief Translator to the Chinese Arsenal. Continued from p. 11.

Mandarin dialect, and always endeavouring to employ the same character for the same sound as far as possible, giving preference to characters most used by previous translators or compilers.

All such invented terms to be regarded merely as provisional and to be discarded if previously existing ones are discovered or better ones can be obtained before the works are published.

3. *Construction of a General Vocabulary of Terms and List of Proper Names.*—During the translation of every book it is necessary that a list of all unusual terms or proper names employed should be carefully kept. These various lists should be gradually collected and formed into a complete volume for general use, as well as with a view to publication.

Unfortunately the above plan has not been thoroughly or consistently carried out, and hence there exists a certain amount of confusion in the works of the different translators already published, and which can only be partially rectified in future editions. This is greatly to be regretted, because the labour that would have been involved would have been trifling compared with the great advantages to be derived. It is to be hoped that the Chinese as well as the foreign members of the department will in time appreciate the necessity of using the same terms invariably throughout the whole series of publications. It is manifest that the practical utility of each one's work depends greatly upon the extent to which the above rules have been observed.

Next to nomenclature it may be well to consider the selection and arrangement of the various works compiled or translated at the Kiangnan Arsenal. The original idea was, as before stated, to prepare an encyclopædia that should bear some resemblance to the "Encyclopædia Britannica." It was soon found, however, that many of the treatises in the eighth edition of that valuable work were too elementary and too far behind the time. It became necessary, therefore, to translate from more modern and complete publications. Various high officials asked to have books translated for them on special subjects. Several treatises not considered sufficiently complete had to be supplemented by larger ones, and hence the idea of an encyclopædia has gradually been almost lost; while a miscellaneous collection of translations and compilations has been the result, and the range of subjects is comparatively limited. In most cases each translator or Chinese writer seems merely to have selected such subjects as suited him best, without regard to the symmetry or harmony of the entire collection. There are thus several important subjects, such as natural history, biography, &c., not yet noticed, while there are various treatises on others of comparatively little importance. As might be expected, military and naval science is one of the subjects that has received a large share of attention.

The general defect about most of the publications is that they are far too elaborate and profound, and consequently can only be understood by a few, while the masses can never master them. It was to remedy this defect that the *Chinese Scientific Magazine* was commenced, although it has no direct connection with this department. Recently some of the English "Science Primers" have been translated by Dr. Allen, and will no doubt help to supply the want. The "School and Textbook Series," however, will probably be the chief means by which a lower and an intermediate grade of books on scientific subjects will be furnished; and although the series owes its origin to the Missionary Conference held in Shanghai in 1877, it has the two European members of the Translation Department on its managing committee. To some extent this series, when completed, will therefore be supplementary to the publications from the Kiangnan Arsenal, and it is arranged that a part, at least, of the series shall be printed at that place.

Next as to the manner in which the work of translation or compilation is carried on. The foreign translator, having first mastered his subject, sits down with the Chinese writer and dictates to him sentence by sentence, consulting with him whenever a difficulty arises as to the way the ideas ought to be expressed in Chinese, or explaining to him any point that happens to be beyond his comprehension. The manuscript is then revised by the Chinese writer, and any errors in style, &c., are corrected by him. In a few cases the translations have been carefully gone over again with the foreign translator, but in most instances such an amount of trouble has been avoided by the native writers, who, as a rule, are able to detect errors of any importance themselves, and who, it must be acknowledged, take great pains to make the style as clear and the information as accurate as possible. A fair copy having been made, the work is placed in the hands of the foreman of the printing department, who causes it to be written out on sheets of thin transparent paper in the large bold book-characters of the "Sung" pattern, and pasted on blocks ready for the engraver. All illustrations, diagrams, &c., are drawn on the same paper by an experienced draughtsman, and cut at the same time and on the same kind of blocks as the characters with which they are interspersed, as in foreign books. In case of steel engravings, such as those accompanying the last edition of Herschel's "Outlines of Astronomy," translated by Mr. Wylie, the illustrations have been printed in England from the original plates. The various charts have been printed from copper plates engraved at the Arsenal.

It may seem strange that with such facilities for printing in Chinese by metal type as exist in Shanghai, and with a complete fount of such type as well as a good cylinder press on the premises, these books are nevertheless cut on wooden blocks and printed by hand, in the old-fashioned way that existed in China for so many ages before printing was known in Europe. The fact is, however, that as a matter of economy and convenience the old system is preferable. The blocks are all of the same size, about eight inches by twelve inches, and about half an inch thick. Each block represents two leaves or four pages of the book, being engraved on both sides. The blocks for a complete work can thus be stowed away in a very small compass. The cost of engraving a page of these wooden blocks is said to be but little more than the expense of setting up a page of Chinese type and preparing it for the press. An edition of one copy can be printed if no more are required, and thus the expense of keeping a large stock of printed books on hand, some of which might eventually have to be sold as waste paper when they grew out of date or revisions had to be made, as is the case among ourselves, is entirely avoided. Any errors or misprints that may be discovered can as a rule be corrected on the blocks with but very little trouble. A skilful printer can print by hand five thousand leaves of two pages each in a day, using no press or machinery whatever. He supplies his own tools and receives as wages about twenty-five dollar cents. a day. The paper ordinarily used is white and of the best quality, although a yellowish kind is also made use of at a reduction of 20 per cent. on the selling price. The books are bound in the usual Chinese style and fastened with white silk thread. They present an appearance which satisfies the taste of the most fastidious native.

To those who regard the Chinese language as incapable of expressing modern Western learning, and who consider European languages to be the only medium by means of which the Chinese can become proficient in the Arts and Sciences, the establishment of the Translation Department necessarily appears to be a useless waste of time and money. To those again who grant the possibility of carrying on the work, but suppose that English is destined to become the universal language at no very distant

period, or even before the close of the present century, this attempt to supply Chinese literature with the results of modern discoveries in science and art must of course appear to be conferring a mere transient advantage.

But it is no difficult matter to see that the translation and publication of books in Chinese as it is carried on at the Kiangnan Arsenal and other places is the great means by which the intellectual stagnation of China is to be broken up. This work must necessarily go on and increase rapidly now that a current of thought has begun to set in. As long as foreigners have any knowledge to impart that is of real advantage to the Chinese, so long will the Chinese make efforts to obtain it; for the more the celestial mind drinks at this fountain the greater will become its thirst for further supplies.

The fact that this Translation Department has been established and kept up so long by the Government argues well for the future prospects of China, as it shows that whatever may be the national pride in her antiquated literature, or whatever may be her attitude towards the diplomatists of foreign powers, or the missionaries of foreign religions, she recognises the fact that knowledge is confined to no nation or country. She is therefore willing to be taught even by the "foreign barbarians" such useful things as she feels she is ignorant of. But she must do this of her own accord and in her own way, or not at all. It is a matter in which she is not to be dictated to, as in the case of treaties or missionary rights. She has freely availed herself of what she has considered beneficial, and has not been sparing in funds to enable knowledge to be disseminated throughout the Empire. This willingness to be taught and to pay for being taught is one of the most hopeful features that has occurred in her intercourse with foreign countries, and is deserving of the highest commendation.

The work at the Translation Department is at present only in its infancy; but enough has been done to establish a foundation upon which a large and important structure will eventually arise. Having been commenced and carried on only in obedience to a natural and instinctive desire for knowledge, it ought to go on harmoniously with the course of events, and prove a powerful lever in the regeneration of China. The large number of copies of works already sold at cost price without any attempt to bring them before the public notice evinces the appreciation of the masses of the people; for a Chinaman is very slow in parting with his dollars for what he does not value or admire, or derive benefit from in some way or other. It would be strange if the knowledge that has only been acquired by such vast expenditure of thought and labour by Western nations did not make its value felt among the Chinese; for by means of these books they can in some things place themselves on a level with foreigners without going through the difficulties attending discoverers and inventors.

It is gratifying to find that some of these translations have already found their way as text-books in the Peking University and in higher kinds of mission schools. For example, the work on Trigonometry has been used to advantage in Mr. Mateer's school at Tangchow, in the Shantung province.

Another cheering feature in connection with the Translation Department is, that it is not the only undertaking of the kind in China. Even before it had fairly commenced, Dr. Martin, the learned president of the Peking University, had begun to publish works on natural science and international law. Both he and his fellow-helpers have since published various works on scientific and diplomatic subjects, which have become very popular and have proved of great utility to the Government. Their translations are of a high standard, and are conducted in a style which renders them acceptable to literary men and officials of the highest grade. It is to be regretted that no detailed account of this important work that has been carried on in Peking for so many years appears to have yet been given to the public. Various other Protestant missionaries have done a great service to the country by their long list of published translations in Chinese. The names of at least half a dozen of them will be handed down to future generations as the foremost pioneers of the spread of Western arts and sciences in the "Flowery Land."

The establishment of Chinese legations at the courts of all the great treaty powers, and the creation of Chinese professorships at the Oxford, London, Paris, and Harvard Universities, are events which show the increasing importance of the study of the Chinese language. It is therefore not in vain to hope that in foreign countries, as well as in China, the work of supplying useful knowledge to the Chinese by means of their own language will eventually be carried on to an extent which may bear some reasonable proportion to the size and needs of the "Middle kingdom."

One of the latest and most promising of the schemes which have a similar object in view to the Translation Department is that previously alluded to, namely, the supplying a series of text-books chiefly for use in mission schools, but still of a character suitable to the wants of the nation at large. The practical working of this scheme was placed in the hands of a committee of six gentlemen, all of whom have already had considerable experience in this kind of labour. A series of fifty-five works has been determined on, which embraces several books of an elementary kind that will, no doubt, do well as introductions to the more elaborate treatises on similar subjects already in existence.

It is, however, to the future that we must look for the chief part of the practical utility of all this translation work. Such a vast nation as the Chinese is not to be started into motion and made to follow in the wake of Western civilisation all at once. Generation after generation will have to come and go before the complete transformation will be effected, and the intellectual as well as the physical resources of the country will be turned to the best account. Hereditary tendencies in a wrong direction are not to be eradicated without a long series of struggles. The system of ignoring everything but the "Four Books" and the "Five Classics" at the Government examinations, which are the passports to the highest offices in the State, is not destined to last for ever. By patiently working, on even the present generation of foreigners engaged in this laborious task of spreading intellectual light may hope to see much good resulting from their efforts. If they do not live to see Western learning occupying the position it ought to do in Government examinations they may yet see it holding a prominent place.

The work of translating and compiling scientific books is for the time being perhaps about as dull and unthankful a task as any foreigner could engage in, especially in such a secluded place as the Kiangnan Arsenal, and under the depressing influences of the climate of this part of China. Nothing but a strong sense of duty and a firm belief that this kind of labour is one of the most effective means, under the Divine guidance, for bringing about the intellectual and moral regeneration of this great country, has sufficed to render endurable the long and weary years and weary hours of close and continuous application which it has involved.

4. *List of Books and Statistics.*—The Translation Department, although established in the year 1868, did not commence the publication of books till the year 1871, when a treatise on Practical Geometry and another on Coal and Coal Mining made their appearance. Up to the present year the number of works published amounts to ninety-eight. These works are contained in 236 volumes, a Chinese volume generally consisting of 120 to 200 pages and representing perhaps on an average about

the same number of pages of an ordinary English work in octavo, with small pica type. Of course the style of the original as well as the style of translation may be such as to render this approximate number rather wide of the mark.

The number of copies of works sold up to the end of June, 1879, amounts to 31,111, representing 83,454 volumes. The number of maps and charts published amounts to twenty-seven sheets. Most of them are adaptations of the charts of the British Admiralty, and were printed from copper plates engraved at the Kiangnan Arsenal. The number already sold is 4,774 sheets.

The sum realised by the sale of books and charts may be estimated at about 17,500 dollars, or roughly 3,500*l*.

The numbers sold up to the present time, though considerable, are nothing compared with what might have been expected among such an extensive population. But with no regular means of communication, no postal or railway arrangements, no agencies, and no advertisements or other means of bringing them into general notice or distributing them, it is easy to understand why more have not already been disposed of.

The various periodicals, such as summaries of foreign news, political essays, &c., are not reckoned in the above numbers. From three to five hundred copies of these books are published and distributed gratuitously to various officials both in the vicinity of Shanghai and in distant provinces.

Forty-four works, representing about 142 volumes, have been translated, and are in various stages of preparation, but the publication is not yet commenced.

Thirteen works which are now in the course of translation and of which thirty-one volumes are already completed.

Forty-three books are to be published by the Committee of the "School and Text-book Series." Most of these works are nearly ready to be placed in the printer's hands.

Various treatises on scientific subjects have been published by Protestant missionaries; but about them it has been impossible to obtain statistics as to the numbers printed and sold.

The following list will give some idea of the number and class of scientific works that have been translated:—

Subjects.	Published.		Translated.		In course of translation.	
	works	vols.	works	vols.	works	vols.
Mathematics, Surveying, &c. ...	22	52	2	8	3	5

THE WILLUGHBY SOCIETY[1]

IT was a happy thought to found an association under the name of Francis Willughby, having for its object the reprinting of scarce ornithological works, thus keeping the name of the writer of "Ornithologiæ Libri Tres" in remembrance and doing a service to the working ornithologist. It is nearly nine years over two centuries since Willughby died (July 3, 1672). About seven years younger than John Ray, he studied at Trinity College, Cambridge, under Ray; but though at first the pupil, he was soon the friend and afterwards the patron of our great English botanist. Belonging to a family of wealth and influence, Willughby soon married (1668), and settled at Middleton Hall, Warwickshire. How hard he must have worked the materials for his great work left at the time of his untimely death amply prove. His second son (the elder died) was created a peer by Queen Anne (Viscount Middleton). An annuity was left to Ray, who edited "The Ornithology," which was printed in London (1676) at the expense of Willughby's widow. Willughby has been called the "father of systematic zoology in this country." The new Willughby Society seems determined to follow in his footsteps.

The reprint in fac-simile of M. Desfontaines's "Mémoire" will be no doubt welcomed by the members, and it is only by members that these reprints can be obtained. Honoured by botanists in the beautiful genus Desfontainea, this account of the birds met by him at Barbary is very rare; and we agree with Prof. Newton that few papers are less accessible to ornithologists than those published by the late Sir A. Smith in the *South African Quarterly Journal*. We trust the Willughby Society will meet with the support it deserves from the members of *Ibis* and from bird-lovers in general.

ZOOLOGY OF THE DUTCH ARCTIC EXPEDITION[1]

A SUPPLEMENTARY number of the *Niederländisches Archiv für Zoologie* just issued is composed of an instalment of five papers describing certain of the animals collected or dredged during the two Arctic voyages of the schooner *William Barents*, together with a list of all the places dredged at, and a map with these and the track marked on it. The ship visited the north of Spitzbergen and the west coast of Novaia Zemlia, and stretched northwards thence almost to Franz-Josef Land. All the dredgings, except two off the north coast of Spitzbergen, were made in the Barents Sea, between Novaia Zemlia and the north of Norway and Bear Island. Dr. R. Horst reports on the Annelids. He found no new species amongst the fifty-one obtained in the Barents Sea. Hjalmar Theel found in the Kara Sea, on the east side of Novaia Zemlia, ninety species. There can be little doubt that the fauna of the two seas, which join in several places, must be nearly identical, yet amongst the thirty-one species from the Barents Sea are fourteen not yet collected in the Kara Sea. The Annelid collection seems to have been rather a meagre one, and must not be taken as representative. The Pycnogonids are described by Dr. P. P. C. Hoek. Examples of these were obtained on fourteen out of the entire thirty dredgings made. They are of eight species, one of which is new. Amongst them is one species of the genus Colossendeis, numerous forms of which were obtained by the *Challenger* in southern latitudes, some attaining there gigantic proportions. The Lamellibranchiata are described by Dr. van Haren Noman, who appends to his paper an important memoir, illustrated by three plates, on the anatomy of the eyes, gills, and other parts of *Pecten Grœnlandicus* and other forms; Dr. A. A. W. Hubrecht contributes a list of the fishes; and Dr. F. A. Jentink a few notes on the field-mouse of Novaia Zemlia, *Curriculus torquatus*, which, unlike all of its allies, turns white in winter. The animal ranges over the whole of Arctic America, Europe, and Asia, and in late geological periods extended as far south as England, Germany, and the basin of the Loire.

DR. HOLUB'S AFRICAN TRAVELS[1]

II.

DR. HOLUB'S third and longest expedition was commenced in March, 1875, and with an account of it the second volume opens. He now proposed to explore Southern Central Africa, and having acquired a great deal of experience during his two previous journeys, was justly in great hopes of success. The route this time selected was first to the Molapo River. As usual great herds of game were from time to time met with, wherever the bush cover was good; then on to his old quarters at Shoshong, where a few days for rest were spent; from Shoshong he journeyed to the great salt-lakes. Elands were now met with, and furnished many a hearty meal. The first salt lake was met on the morning of April the 18th. Away to the west it extended as far as the eye could see, and it took two hours to travel the length of its eastern coast. There was a uniform depth of barely two feet, and it presented a light grey surface edged with stiff arrow-grass and surrounded by dense bush-forest, whilst around about it, in the very thickest of the grass, were considerable numbers of miniature salt-pans; indeed every depression in the soil contained salt. The evaporation appeared to be most rapid. This salt-lake was called Tsitane, the same name being also given to the adjoining river. Here the first Baobab tree was seen; it was a fine specimen, some twenty-five feet in height and nearly fifty-two feet in circumference. Another larger and deeper lake was called by the natives Karri-karri. Here baobabs abounded. The third of the great salt-lakes, called Soa, is the largest; it extends westward beyond Lake N'gami; it is also very shallow, being only four feet in depth. Travelling on to the banks of the Nata and to Tamasetze with the object of getting to the Zambesi before the middle of the month, he encountered one of Mr. Anderson's servants called Saul. He was out on an ostrich hunt, and though an uncommonly bad shot, managed in the following manner to get more than his fair share of birds and eggs:—"I always," he told Dr. Holub, "take a man with me, and we look about till we discover a nest, and then we dig a hole pretty close to it in which we hide. The birds come to sit, and it doesn't want a very good shot to knock over an ostrich when it is just at hand. Well, having made sure of one bird, we stick up its skin on a pole near the nest, and except we are seen, and so scare the birds away, a second ostrich is soon decoyed, and I get another chance." Such "hunting" as this is very likely to destroy the flocks of ostriches in the country around the Klamaklenyana Springs. The country of the Madenassanas was now entered. These people would seem to be serfs to the Bamangwatos. They are a fierce race, tall, and strongly built, the men generally with repulsive countenances, though occasionally some of the women were even nice looking. Their skin is almost black, and their stiff woolly hair hangs down for more than an inch over their temples, while it is either quite short or is kept quite short over the rest of the skull. Many elephant-hunting parties were met with. One trader had in his two waggons not less than 7000 lbs. of ivory, procured mostly in the district between the Victoria Falls and the mouth of the Chobe. A very short *détour* off the beaten waggon-track revealed herds of buffaloes, striped gnus, Zulu hartebeests, and zebras, or showed evident tracks of these and lions. Great trees with trunks of sixty feet in height were also met with, and a great many orchids with *red* blossoms. What a pity that Dr. Holub did not bring home some of these! Passing over an account of a rather exciting lion-hunt, in which both lion and lioness got decidedly the better of it, the Jamasetze wood was left on July 20. The author was much struck by the peculiar way in which some of the leguminous trees shed their seeds, the heat of the sun causing the pods to burst with a loud explosion and to cast the seeds to a considerable distance all about. The air near this wood was full of myriads of tiny bees that crept into one's clothes, hair, and ears, making even one's nose tingle with great discomfort. About August the 10th the watershed of the Zambesi district was reached, and, gazing down into the valleys of the Chobe and the Zambesi, the author saw the realisation of some of the dreams of his youth. At Impalera, the Lower Chobe and the Zambesi rivers were calculated to have a depth of between thirty and forty feet, but the reaches and the rapids make all navigation impracticable.

Having obtained permission from the king, the Marutze kingdom was visited. Hippopotami and crocodiles were found abundant in the rivers, but all such creatures had to be for the moment overlooked because King Sepopo was waiting to receive the white man. At the banquet fish of many sorts seems to have been the principal food;

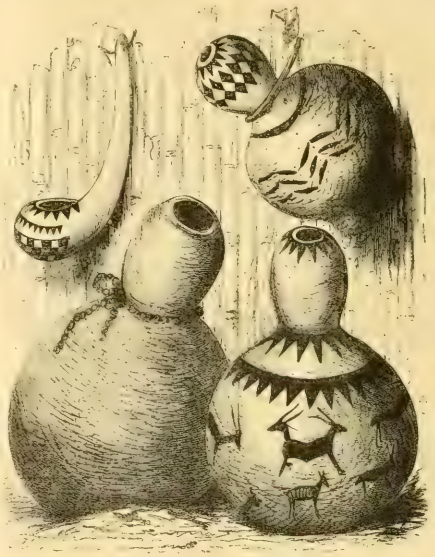

FIG. 4.—Ladle and Calabashes.

but at a supper also given, boiled eland flesh was served with a sauce made of meal, and the drink was impote (honey beer). The king demanded no present, though, such being usual, Holub presented him with a Snider breech-loader and 200 cartridges. A good deal of interesting details are given about the kingdom of Marutze, which now extends along both sides of the Zambesi, from Sekhose, to about 150 miles south of the confluence of the Kabompo and the Liba. It is a most productive portion of Africa, as well adapted for agriculture as for cattle breeding, abounds in game, and seems prolific in vegetable products, of which indiarubber is not the least important.

Not at once getting the king's permission to pursue his journey to the source of the Zambesi, Dr. Holub returns to Panda Ma Tenka, and then accompanied his friends Westbeech and Francis on a visit to the Victoria Falls, which were about fifty miles off, which are declared to be, so far as the author's experience goes, the most imposing

[1] "Seven Years in South Africa. Travels, Researches, and Hunting Adventures between the Diamond Fields and the Zambesi." By Dr. Emil Holub (translated by Ellen E. Frewer). With about 200 original illustrations and a map. In two volumes. (London: Sampson Low, Marston, Searle, and Rivington, 1881.) Continued from p. 38.

phenomena in the world. Staying there three days, after the amusement of a lion hunt and several adventures, they returned on September 24 to Panda Ma Tenka. With somewhat failing health our author once again turned his face to the sources of the Zambesi; but when he got to Sesheke the king told him he had been too long in coming, that it was too late to go now, and he had not kept the guides waiting for him. The king declared it would take him over four months to reach the Zambesi sources in the kingdom of the Iwanyoe. An elephant hunt on a grand scale took place about this time, but ended in a panic, during which the whole herd of elephants escaped; but a lion hunt was more successful. Dr. Holub says he heard that one of the days during another great elephant hunt a herd of over a hundred elephants had been seen, but although at least 10,000 bullets had been fired off, only four elephants had been killed. At last leave was given to the author to accompany some of the queens who had come from the Barotse country, and on December 1 he was off. Three royal canoes were placed at his disposal, but he had to ask for a fourth, and even then his servants had to proceed on foot along the banks. The Barotse rapids were safely ascended, but at the rapids known as Mutshila Aumsinga one of the canoes, that which carried all his provisions, gunpowder, medicines, and natural history collections, was capsized, and this ended all his schemes of penetrating far into the country; and thus the preparations of seven previous years proved fruitless. The severe wetting and the extreme disappointment, brought on a dangerous attack of fever, and, growing worse and worse, there was finally no alternative but to return. After a long delay at Sesheke in hopes of recovery he was compelled, after some weeks, to revisit Panda Ma Tenka. An interesting account is given of the manners and customs of the Marutze tribes. They seem to believe in a Supreme Being in good and evil spirits, in the continued existence after death; they are fair agriculturists and good cattle breeders, having a fertile soil, a genial climate, and abundance of water; though the tsetse fly is met with, game abounds; Kaffir corn, maize, beans, cotton, and tobacco are cultivated; salt is expensive; beer from corn is usually drunk at meals; they have also a cider-like drink and the honey beer. The people are cleanly in their persons and keep their food material in well-washed wooden or earthenware bowls or in suitable baskets or calabashes. Some of these are very tastefully decorated, and in the accompanying figures (Fig. 4) one will be seen with animal designs. The medical knowledge of the Marutze would appear to be in advance of many of the South African tribes; they know the properties of a number of medicinal or poisonous plants; the treatment of fever, coughs, and wounds. Bleeding was a common operation among them, and was employed in cases of neuralgia or to reduce inflammation.

FIG. 5.—Rock caves and inscriptions of Bushmen.

After many troubles and trials Panda Ma Tenka was

left, and the return journey was made by the way of the Makalaka and West Matabele countries, and a hearty welcome was given to the traveller on his arriving at Shoshong by the Mackenzies. While here the news arrived that war had broken out in the Transvaal between the Boers and Sekokuni. The journey to the Diamond Fields was made by Limpopo, and shortly Kimberley was for the fourth time reached. Settling at Bullfontein, the doctor with indefatigable energy soon got into large practice, and during two years, surrounded by the various animals and birds he had collected in this journey, his establishment was quite a menagerie. One holiday he paid a visit to the Orange Free State. When he viewed the Rocky Caves used by the Bushmen, he was particularly attracted by the remarkable carvings on the rocks done by the Bushmen to adorn their primitive abodes. A sketch of some of these is represented in the adjoining woodcut (Fig. 5). The rock is chiefly a sandstone, and the drawings are frequently executed in coloured ochres.

After a considerable period spent at Bullfontein, at Grahamstown, at Port Elizabeth, and at Cape Town, he embarked on board the *Germania* for Europe in August, 1879, bringing with him large ethnological and natural history collections. While the author's travels have added something to our previous knowledge of the geography of the portions of Africa he traversed, his account of them is really pleasant reading, and will be found of special interest to the naturalist and sportsman.

ELECTRIC LIGHTING [1]

III.

DECIDEDLY the most successful application of the electric light in London is at the Cannon Street station of the South Eastern Railway. The Charing Cross station of that Company has been lit up by the Brush system, and the Bricklayers' Arms goods-yards and sheds by Mr. Crompton's system, so that the South Eastern Railway officials have an admirable competitive trial proceeding within easy reach of inspection. The Cannon Street station is lit up by the British Electric Light Company with Gramme machines and Brockie lamps.

The engine—one of Marshall's semi-portable type—is of 14 horse-power nominal, and has a double cylinder on a locomotive boiler. The power is transferred by countershafting to the dynamo-machines by a system specially designed for the purpose, which is shown in the following sketch (Fig. 2). Large heavy fly-wheel pulleys give a second motion to the fly-wheel, which secures great steadiness—an essential feature of electric lighting. The engine is controlled by Hartnell's automatic governor, which regulates the expansion-gear of the engine and secures great uniformity of action.

The dynamo-machines are of a new class of Gramme, of high electromotive force, and they generate currents powerful enough to work five lamps. The current produced is of 26 webers strength, and works a circuit of about 8 ohms resistance, thus giving an electromotive force of 208 volts. There are two machines at work, working ten lamps—eight being inside the station and two outside. The dynamos are fed by smaller Grammes, as shown in Fig. 2.

The lamps are Brockie's, the mechanism of which is extremely simple, consisting only of one magnet with a clutch, which, by means of a branch circuit, periodically interrupted by the commutator, readjusts the arc by letting the clutch fall, which releases the carbons and brings them momentarily together, and then picks them up again very smartly, so as to separate them the required distance. This gives the lamp a blinking habit,

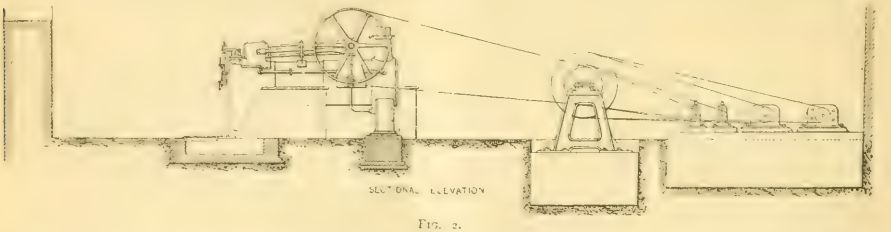

FIG. 2.

which at first is peculiar, but which one soon gets accustomed to and ignores. The diagram (Fig. 3) clearly illustrates how this is done. The magnets are fixed on shunts, two lamps being on two shunts and one lamp on the other. The shunts are of smaller wire than that of the main circuit, but they do not interfere with the main current, which passes through the carbons—in fact the shunts reduce the total resistance of the circuit. The lamps burn for four and a half hours, but it is intended to introduce a double set of carbons, which will of course duplicate this time.

Mr. Brockie has introduced quite a new principle into electric lighting, and certainly, to judge from the effect at Cannon Street, his success is unqualified. It remains to be seen how far this success is repeated at the General Post Office, at Victoria Street, Manchester, at Prince's Dock, Liverpool, and in the town of Liverpool itself. We certainly would like to see a good west-end street, say Piccadilly, Regent Street, or the Haymarket, lit up by this system.

Another system, not yet extensively employed, is Joel's improved incandescent electric lamp. In the latter part of 1878 considerable interest was excited in both scientific and commercial circles by the announcement that M. Werdermann had succeeded in the so-called division of the electric light by an invention based on the incandescent principle. His system was exhibited on an experimental scale only for some time, and then suddenly disappeared from public notice.

This incandescent principle has recently been revived, with many and ingenious improvements in the mechanism of the lamp, by Mr. Joel. An illustration of the hanging lamp is shown in Fig. 4. The light is reproduced, as was the case in M. Werdermann's system, by the heating to incandescence of the end of a small rod or pencil of carbon forming one electrode, which protrudes through a pair of contact jaws and abuts upon a fixed cylinder of copper forming the other electrode. The carbon pencil consumes at the rate of 2½ to 3 inches per hour for lights of 100 candle-power and upwards, and is fed forward according to the consumption. The length of carbon in circuit between the contact jaws and the fixed electrode is about three-quarters of an inch, and this, by the passage of the

[1] Concluded from p. 35.

current, is rendered highly incandescent, chiefly however at that part near the copper electrode, where the pencil becomes pointed, and therefore more intensely heated. There is also, in addition to this, a glow or flame-like appearance from the sides of the consuming carbon to the copper electrode, the light thus apparently taking an intermediate position between the purely incandescent system and that of the arc. The heated point of carbon becomes curled at the tip in a peculiar manner, as though it were viscous in shape, somewhat like a mushroom where it wastes away, and is replaced by the gradual forward motion of the pencil.

The fixed electrode, which may be entirely of copper or with a graphite insertion, remains intact without any appreciable wear.

The chief improvements in this lamp consist in the simplification and certainty of action of the mechanism in connection with the contact jaws for clamping the carbon pencil, by which means the lateral pressure of the jaws and the feeding of the carbon are attained by the combined action of one actuating weight, as shown in the diagram, Fig. 5. It will be seen from this that the lateral pressure is thus always proportional to the downward pressure, and may be varied to suit any conditions. The details devised for rendering the lamps in the same circuit independent of each other, and its general adaptability for interior and domestic lighting, constitute an important advance on anything which has gone before.

On referring to the sectional view of the lamp, Fig. 5, E is the fixed copper electrode upon which abuts the point

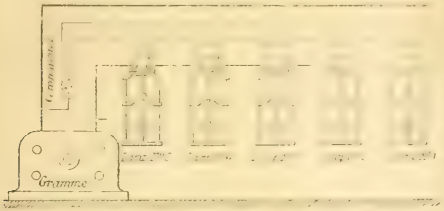

FIG. 3.

of the carbon *e*, which is rendered intensely incandescent by the passage of the current between the jaws and the copper cylinder. The jaws are shown at J clamping the carbon pencil. The actuating weight, W, which gives both the feeding motion to the pencil as it consumes, and the lateral pressure to the jaws, is suspended by continuous cords to the top of the lamp B, the cords then passing down through the weight and under one of the rollers at R, up again through a roller attached to the carbon holder, then back again through another roller at R, and ending at the weight. The rollers R are attached to a light tube, P, which passes down through a nipple, N, and terminates in a flange under the horizontal arms of the jaws and lifts them according to the leverage, thus producing the lateral pressure on the pencil. The top of this tube has also attached to it the armature, A, of an electro-magnet S, wound with fine wire and arranged in a shunted circuit in such a manner that as long as the normal condition of the light is maintained it is neutral; but if an arc should be accidentally formed between the carbon *e* and the copper E, the electro-magnet comes into action in opposition to the controlling weight, and frees the jaws from lateral pressure, thereby allowing the carbon pencil to descend freely and establish contact.

The carbon-holder is also arranged (Fig. 6) so that when the pencil is very nearly consumed the lamp is automatically short-circuited by the lever at L making contact with the arm carrying the copper electrode.

The stem or body of the lamp forms an important part of the whole, being formed of metal tubing in two semi-circular halves, each half forming part of the electrical circuit, the current traversing one side, of which the jaws form part, passing through the carbon pencil to the copper electrode, and returning by the other side of the lamp.

The two sides are kept closed mechanically (but insulated electrically from each other) by the latch and knob T, Fig. 5, which also automatically short-circuits the lamp when opened for the purpose of putting in fresh carbon, thus rendering it perfectly safe in handling. There are

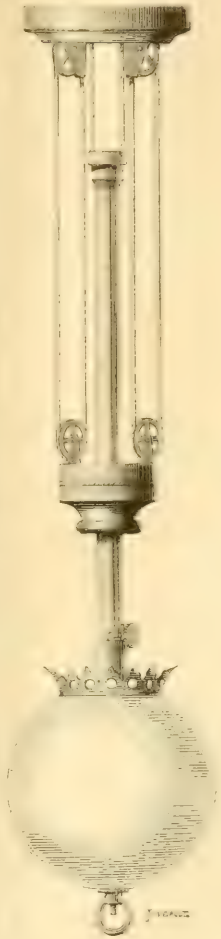

FIG. 4.

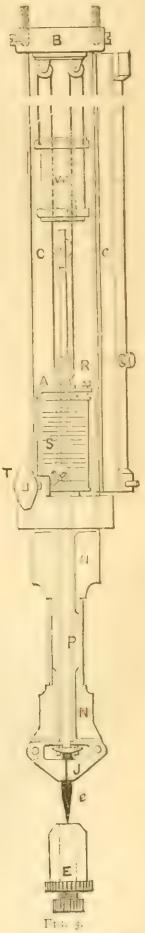

FIG. 5.

ingenious arrangements attached to this system for switching a lamp on or off, with resistances equivalent to that of the lamp; but upon these it is unnecessary to dwell, these adjuncts being common to many systems.

Prof. Adams stated at the Society of Arts that with this system an illuminating power of 715 candles per horse-power could be obtained.

If incandescent lighting is more expensive than the

arc system, which it necessarily is when the current has to traverse a number of small lights, it has the great advantage of possessing perfect steadiness, which an arc lamp can never rival, and for interior lighting this is of great importance. The cost of carbons constitutes an important item in the expenses attached to electric lighting as now employed, and if we consider that in some incandescent systems the consumption of material is for a considerable period nothing at all, we may still work economically even though using considerably more horse-power to obtain our results.

Incandescent lamps, however, as at present constructed, are limited to small lights and a certain steady strength of current, as any sudden increase is apt to break the thin carbon filament employed. In addition to this it is necessary to protect the incandescent carbon of such lamps from the influence or access of oxygen, as it would be rapidly consumed by even the slightest amount of oxygen present. Therefore it must be protected by inclosing it in a vacuum, and it is a matter of considerable difficulty to produce a sufficiently perfect vacuum to prevent some small quantity of free oxygen from coming into contact with the light-giving material. Incandescent lamps are very capricious. Difficulties arise from the extreme thinness and delicacy of the glass employed, leakage from defective sealing or fractures, the liability of the incandescent material to shake loose in its supports,

Fig. 6.

and the great care required in manipulation. The Joel lamp is free from these objections, and as in lamps that are purely incandescent, the heat is produced by the current only (the carbon not undergoing combustion by reason of the absence of oxygen), it follows that the incandescent portion cannot attain so high a temperature as when the carbon consumes, and therefore the light must necessarily be of less power than that in the lamp described. The offices of the Electric Light Agency in Queen Victoria Street are lighted by this system, and in the workshop two of these lamps take the place of fifteen gas jets with highly satisfactory results. The carbons employed are of 5 mm. diameter, and in length of about 1 m. The lamp burns for seven or fourteen hours, according to the dimensions of the carbon.

The Swan lamp is the only purely incandescent lamp that has met with any success in England. The Maxim light, the most successful in America, has not reached here yet. Dr. Draper's house in New York is lit by it, and he is able to manipulate his lamps with all the ease and comfort of gas-fittings. Sir William Armstrong, at Craigside, near Newcastle, has utilised a brook to run a dynamo-machine by means of a turbine, and he is able to maintain thirty-seven Swan-lights in his house. Mr. Spottiswoode occasionally gratifies his friends by illuminating his rooms with Swan-lights, and the rooms of the Royal Society were so lit at their last *soirée*. But such lamps remain luxuries, and nothing more.

Wherever the electric light has been introduced for internal illumination it has met with considerable favour. It not only lowers the temperature of a gas-lit room within reasonable bounds, but it clears the atmosphere of vitiations, and men work more cheerfully and better. In fact the extra amount of work got out of men is said in some instances to pay for the change. Moreover, since it renders the illumination comparable with that of daylight, it enables the aged and the weak-sighted to read and work without spectacles.

Electric lighting has however passed the experimental, it has now reached the practical stage.

HOW TO PREVENT DROWNING

I WISH to show how drowning might, under ordinary circumstances, be avoided even in the case of persons otherwise wholly ignorant of what is called the art of swimming. The numerous frightful casualties render every working suggestion of importance, and that which I here offer I venture to think is entirely available.

When one of the inferior animals takes the water, falls, or is thrown in, it instantly begins to walk as it does when out of the water. But when a man who cannot "swim" falls into the water, he makes a few spasmodic struggles, throws up his arms, and drowns. The brute, on the other hand, treads water, remains on the surface, and is virtually insubmergible. In order then to escape drowning it is only necessary to do as the brute does, and that is to tread or walk the water. The brute has no advantage in regard of his relative weight, in respect of the water, over man, and yet the man perishes while the brute lives. Nevertheless any man, any woman, any child who can walk on the land may also walk in the water just as readily as the animal does, if only he will, and that without any prior instruction or drilling whatever. Throw a dog into the water and he treads or walks the water instantly, and there is no imaginable reason why a human being under like circumstances should not do as the dog does.

The brute indeed walks in the water instinctively, whereas the man has to be told. The ignorance of so simple a possibility, namely the possibility of treading water, strikes me as one of the most singular things in the history of man, and speaks very little indeed for his intelligence. He is, in fact, as ignorant on the subject as is the newborn babe. Perhaps something is to be ascribed to the vague meaning which is attached to the word swim. When a man swims it means one thing, when a dog swims it means another and quite a different act. The dog is wholly incapable of swimming as a man swims, but nothing is more certain than that a man is capable of swimming, and on the instant, too as a dog swims, without any previous training or instruction, and that by so doing without fear or hesitancy, he will be just as safe in the water as the dog is.

The brute in the water continues to go on all fours, and the man who wishes to save his life and cannot otherwise swim, must do so too, striking alternately, one two, one two, but without hurry or precipitation, with hand and foot, exactly as the brute does. Whether he be provided with paw or hoof, the brute swims with the greatest ease and buoyancy. The human being, if he will, can do so too, with the further immense advantage of having a paddle-formed hand, and of being able to rest himself when tired, by floating, a thing of which the animal has no conception. Bridget Money, a poor Irish emigrant, saved her own life and her three children's lives, when the steamer conveying them took fire on Lake Erie, by floating herself, and making them float, which simply consists in lying quite still, with the mouth shut and the head thrown well back in the water. The dog, the horse, the cow, the swine, the deer, and even the cat, all take to the water on occasion, and sustain themselves perfectly

without any prior experience whatever. Nothing is less difficult, whether for man or brute, than to tread water, even for the first time. I have done so often, using the feet alone or the hands alone, or the whole four, many times, with perhaps one of my children on my back. Once I recollect being carried a good way out to sea by the receding tide at Boulogne, but regained the shore without difficulty. A drop of water once passed through the rima of the glottis, and on another occasion I experienced such sudden indisposition that if I had been unable to float, it must, I think, have gone hard with me.

Men and animals are able to sustain themselves for long distances in the water, and would do so much oftener were they not incapacitated, in regard of the former at least, by sheer terror, as well as complete ignorance of their real powers. Webb's wonderful endurance will never be forgotten. But there are other instances only less remarkable. Some years since, the second mate of a ship fell overboard while in the act of fisting a sail. It was blowing fresh; the time was night, and the place some miles out in the stormy German Ocean. The hardy fellow nevertheless managed to gain the English coast. Brock, with a dozen other pilots, was plying for fares by Yarmouth; and as the main-sheet was belayed, a sudden puff of wind upset the boat, when presently all perished except Brock himself, who, from four in the afternoon of an October evening to one the next morning, swam thirteen miles before he was able to hail a vessel at anchor in the offing. Animals themselves are capable of swimming immense distances, although unable to rest by the way. A dog recently swam thirty miles in America in order to rejoin his master. A mule and a dog washed overboard during a gale in the Bay of Biscay have been known to make their way to shore. A dog swam ashore with a letter in his mouth at the Cape of Good Hope. The crew of the ship to which the dog belonged all perished, which they need not have done had they only ventured to tread water as the dog did. As a certain ship was labouring heavily in the trough of the sea, it was found needful, in order to lighten the vessel, to throw some troop-horses overboard which had been taken in at Corunna. The poor things, my informant, a staff-surgeon, told me, when they found themselves abandoned, faced round and swam for miles after the vessel. A man on the east coast of Lincolnshire saved quite a number of lives by swimming out on horseback to vessels in distress. He commonly rode an old grey mare, but when the mare was not to hand he took the first horse that offered.

The loss of life from shipwreck, boating, bathing, skating, fishing, and accidental immersion is so disastrously great, that every feasible procedure calculated to avert it ought to be had recourse to. People will not consent to wear life-preservers, but if they only knew that in their own limbs, properly used, they possessed the most efficient of life-preservers, they would most likely avail themselves of them. In every school, every house, there ought to be a slate tank of sufficient depth, with a trickle of water at one end and a syphon at the other, in order to keep the contents pure. A pail or two of hot water would at any time render the contents sufficiently warm. In such a tank every child from the time it could walk ought to be made to tread water daily. Every adult, when the opportunity presents itself, should do so. The printed injunction should be pasted up on all boat-houses, on every boat, at every bathing place, and in every school. "Tread water when you find yourself out of your depth" is all that need be said, unless indeed we add, "Float when you are tired." Every one, of whatever age or sex, or however encumbered with clothing, might tread water with at least as much facility, even in a breaking sea, as a four-footed animal does. The position of a person who treads water is, in other respects, very much safer and better than is the sprawling attitude which we assume in ordinary swimming. And then the beauty of it is that we can tread water without any preliminary teaching, whereas "to swim" involves time and pains, entails considerable fatigue, and is very seldom adequately acquired after all.

The Indians on the Missouri River, when they have occasion to traverse that impetuous stream, invariably tread water just as the dog treads it. The natives of Joanna, an island on the coast of Madagascar, young persons of both sexes, walk the water carrying fruit and vegetables to ships becalmed, or it may be lying-to, in the offing miles away. Some Croomen whose canoe upset before my eyes in the seaway on the coast of Africa walked the water, to the safe-keeping of their lives, with the utmost facility; and I witnessed negro children on other occasions doing so at a very tender age. At Madras, watching their opportunity, messengers, with letters secured in an oilskin cap, plunge into the boiling surf, and make their way, treading the water, to the vessels outside, through a sea in which an ordinary European boat will not live. At the Cape of Good Hope men used to proceed to the vessels in the offing through the mountain billows, treading the water as they went with the utmost security. And yet here, on our own shores, and amid smooth waters, men, women, and children perish like flies annually, when a little properly-directed effort—treading the water as I have said—would haply suffice to rescue them every one.

Belfast HENRY MACCORMAC

NOTES

WE learn from the *Times* that at the meeting of the Royal Society on Thursday last the vacancies in the list of foreign members were filled by the election of Gabriel Auguste Daubrée of Paris, Jean Charles Marignac of Geneva, Carl Nägeli of Munich, and Carl Weierstrass of Berlin.

SIR JOHN LUBBOCK has been nominated to succeed Prof. Allman as president of the Linnean Society, and Mr. G. J. Romanes for the post of zoological secretary, vacant by Mr. Alston's lamented death.

IN the current number of the *Revue Scientifique* there is an article by M. de Lacaze-Duthiers descriptive of an interesting enterprise on which he is engaged, viz. the construction of a zoological laboratory at Port Vendres. Backed by the recommendation of the Academy of Sciences, he obtained a liberal offer from the municipal authorities of the place, which among other considerations determined him in the selection of the site. Altogether he is provided with 32,000 francs as a capital sum, 750 francs per annum as a fixed income, with the gift of building ground and a boat. It will thus be seen that the municipal authorities deserve all credit for the substantial encouragement which they have extended to the undertaking. In a few months the laboratory will be completed, and is then to be thrown open to workers of all nationalities. As its situation on the coast of the Mediterranean is an admirable one for the procuring of fauna, the institution is in every way favourably circumstanced, and we cordially wish it all success.

THE English Transit of Venus Commission having expressed a desire for an understanding with the French Commission, so as to secure a uniform method of observation, M. d'Abbadie and M. Tisserand are coming to London to compare notes with the English Commission.

A LETTER from M. Mascart, director of the French Central Meteorological Bureau, read at last week's meeting of the Paris Academy of Sciences, stated that the French Government intend to establish an observatory for terrestrial magnetism at Cape Horn. The expedition will set out in the same vessel as will

take the astronomers who are to observe the approaching transit of Venus. This is intended as the contribution of France to the international scheme of polar observations, to which England has as yet made no sign of lending her aid.

Messrs. Siemens and Halske gave a public trial last week of their new electric railway, which runs between Lichterfelde and the Cadettenhaus, about six miles from Berlin. The trial is stated to have been most successful. It was in a simple tram-car, with an electric battery totally concealed between the wheels, in connection, through the rails it ran on, with the principal battery at the station. The rails are three feet three inches apart, and exactly resemble those of an ordinary railroad, only the gauge being narrower. The greatest speed obtained on a distance of about one and a half mile was eighteen English miles an hour. Dr. Siemens has proved that if necessary a far greater speed could be obtained, but this is not allowed by the German police authorities. It will not be allowed to proceed at more than nine miles per hour. The railway was opened to the public on Monday.

M. Pouchet with two assistants are about to proceed to Vadsö, on the east coast of Finmark, to collect natural history specimens for the Paris Museum of Natural History.

An interesting paper on recent earthquakes in Japan has lately been published by Prof. John Milne, vice-president of the Seismological Society of Japan. To get an arrangement which will cause a clock to stop at exactly the same tremor during an earthquake as another similar clock is stopped at, to get a complete time record of the tremors at any place, and to find accurately the direction of the transmission of earth vibrations, these are the questions which Mr. Milne and his friends have been trying to surmount with the help of a grant of money from the British Association and the help of the Japanese Telegraph Department. A result of the work hitherto done is that there is a chronic centre of disturbance within a radius of a few miles from Yokohama, and Mr. Milne felicitates the inhabitants of that seaport on the advantages which their position gives them for seismological observation. The Society has also issued useful forms in which to record earthquake observations, which might supply hints to European observers.

At the Victoria (Philosophical) Institute, on Monday, a paper on "The Rainfall and Climate of India" was read by Sir Joseph Fayrer, K.C.S.I., F.R.S. He reviewed the causes and effects of those climatic changes which obtain in that country at the present time, and many of which once operated in Palestine and Egypt, not to mention England and other parts of the world, and threw light on questions involving the denudation theory, the variation of river deposits, and other matters affecting the uniformitarian theory of geology. Sir Joseph Fayrer spoke at some length in regard to the climate of India, and showed that, if what science had taught us in regard to the effects of cultivation, the preservation of the forests, drainage, &c., were carefully attended to by the powers that be, the importance of the results could not be estimated, as they involved the health and prosperity of that great country.

In connection with the subject of "Fascination," Dr. Otto of Schemnitz, Hungary, writes us of a case which came under his notice. In 1859, when the use of firearms was under stringent regulations in Hungary, peasants often killed hares on the Danubian island Creppel in the following way:—Two peasants would drive in a cart over the reaped fields. On spying a hare (say at two to three hundred paces) they proceeded to drive round it some five or six times in succession. One peasant carrying a long stick at length sprang out, at the moment the cart was behind the hare (the cart continuing its course), and coming up to the animal slowly, killed it without difficulty. It was not uncommon to kill thus as many as six or seven hares in one morning.

The following instance of animal intelligence is sent to us by Dr. John Rae, F.R.S., who states that the Mr. William Sinclair mentioned is respectable and trustworthy. The anecdote is taken from the *Orkney Herald* of May 11:—"A well-authenticated and extraordinary case of the sagacity of the Shetland pony has just come under our notice. A year or two ago Mr. William Sinclair, pupil teacher, Holm, imported one of these little animals from Shetland on which to ride to and from school, his residence being at a considerable distance from the school buildings. Up to that time the animal had been unshod, but some time afterwards Mr. Sinclair had it shod by Mr. Pratt, the parish blacksmith. The other day Mr. Pratt, whose smithy is a long distance from Mr. Sinclair's house, saw the pony, without halter or anything upon it, walking up to where he was working. Thinking the animal had strayed from home, he drove it off, throwing stones after the beast to make it run homewards. This had the desired effect for a short time; but Mr. Pratt had only got fairly at work once more in the smithy when the pony's head again made its appearance at the door. On proceeding a second time outside, to drive the pony away, Mr. Pratt, with a blacksmith's instinct, took a look at the pony's feet, when he observed that one of its shoes had been lost. Having made a shoe he put it on, and then waited to see what the animal would do. For a moment it looked at the blacksmith as if asking whether he was done, then pawed once or twice to see if the newly-shod foot was comfortable, and finally gave a pleased neigh, erected its head, and started homewards at a brisk trot. The owner was also exceedingly surprised to find the animal at home completely shod the same evening, and it was only on calling at the smithy some days afterwards that he learned the full extent of his pony's sagacity."

M. J. Plateau has issued a second supplement to the "Bibliographie Analytique des Principaux Phènomenés Subjectifs de la Vision," comprising the years 1878-79. It is reprinted in a separate form from the *Memoirs* of the Belgian Academy.

We have received the first three parts of the *Zeitschrift für Instrumentenkunde*, a monthly journal intended to bring together all novelties in scientific apparatus. It is edited by Dr. George Schwiskus, assisted by a large staff, and published by Julius Springer of Berlin. It is amply illustrated and its utility is obvious.

M. Carnot, the grandson of the celebrated War Minister of the First Republic, has taken an important step in his capacity of Minister of French Public Works. He sent to the Lower House a *projet de loi* asking for a credit of 280,000*l.* in order to introduce at once into all the French lighthouses magneto-electric generators and acoustical signals with steam blower. This proposal is sure to be accepted with enthusiasm, and executed with the utmost rapidity.

The General Council of the Seine have granted the credits asked by the Préfet for establishing in the Morgue a refrigerating machine by MM. Mignon and Rouard. Ammonia is the substance which has been considered as the most powerful and cheapest by a special commission appointed by the Council of Hygiene. Laboratories will be annexed to the establishment. The work will begin as soon as Parliament has voted a small sum for contributing to the expense.

M. Barthélemy St. Hilaire, French Minister of Foreign Affairs, has recommended to M. Cochéry a suggestion of M. W. de Fonvielle's advising the appointment of a commission on the state of international law relating to ocean telegraphic cables, and the means of improving it. M. St. Hilaire states that in

case the Congress of Electricians comes to any conclusion relating to this most important object, he is ready to send a circular to the several Governments on the opening of an international conference on the matter. This official correspondence will be published in full in the next number of *L'Électricité*.

We take the following from the *Colonies and India*:—"To say that a train had been stopped by caterpillars would sound like a Yankee yarn, yet such a thing (according to the *Rangitikei Advocate*) actually took place on the local railway a few days ago. In the neighbourhood of Turakina, New Zealand, an army of caterpillars, hundreds of thousands strong, was marching across the line, bound for a new field of oats, when the train came along. Thousands of the creeping vermin were crushed by the wheels of the engine, and suddenly the train came to a dead stop. On examination it was found that the wheels of the engine had become so greasy that they kept on revolving without advancing—they could not grip the rails. The guard and the engine-driver procured sand and strewed it on the rails, and the train made a fresh start, but it was found that during the stoppage caterpillars in thousands had crawled all over the engine, and over all the carriages inside and out."

A shock of earthquake is reported from Möttling (Carniola) on April 26, at 4.55 p.m., direction from north to south. At Tüffers (Styria) a smart shock was felt on May 6, at 7.41 p.m., duration three seconds, direction north-east to south-west.

On Tuesday last week, the Princess Christian of Schleswig-Holstein presented the prizes and certificates adjudged to candidates in a competitive examination on "Domestic Sanitation," following a course of lectures delivered on the subject by Dr. B. W. Richardson. With regard to the course of lectures he had given at the request of the Ladies' Sanitary Association, Dr. Richardson stated that nearly 300 pupils attended, of whom seventy-five competed for the prizes offered by Mr. Edwin Chadwick and others. Of the papers sent in, he could say that all the writers showed a sound knowledge of four subjects, viz. the relative values of the substances used as foods, the circulation of the blood, the process of breathing, with the conditions which produce a pure and healthy dwelling, and the management of a sick room. Dr. Richardson announced that, by desire of the Ladies' Sanitary Association, he should deliver another course of lectures, beginning in October next, on the nervous system. This would raise questions concerning education and other interesting and, at present, debatable matters.

In the *Revue Scientifique* for May 14 is the conclusion of a long paper on the Physiological Immunities enjoyed by the Jewish race, in which the nature of these immunities is examined and the probable reasons for them given.

The additions to the Zoological Society's Gardens during the past week include an Indian Fruit Bat (*Pteropus medius*) from India, presented by Mr. Edwin H. Maskell; a Wood Brocket (*Cariacus nemorivagus*) from South America, presented by Capt. Mackenzie, s.s. *Severn*; an Egyptian Gazelle (*Gazella dorcas*) from Egypt, presented by Mrs. J. J. Jones; a Common Hare (*Lepus europæus*), British, presented by Mr. Wormald, F.Z.S.; two Hawfinches (*Coccothraustes vulgaris*), British, presented by Dr. Bree; three Viperine Snakes (*Tropidonotus viperinus*) from North Africa, presented by Mr. J. C. Church; a Common Adder (*Vipera berus*), British, presented by Mr. G. H. King; a Three-striped Paradoxure (*Paradoxurus trivirgatus*) from India, a Javan Adjutant (*Leptoptilus javanicus*) from Java, received in exchange; six Rose-coloured Pastors (*Pastor roseus*) from India, two Mandarin Ducks (*Aix galericulata*) from China, purchased; a Blue and Yellow Macaw (*Ara ararauna*) from South America, deposited; a Geoffroy's Dove (*Peristera geoffroii*), three Red-crested Whistling Ducks (*Fuligula rufina*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN

Variable Stars.—Mira Ceti, which was at its minimum on March 20, according to Prof. Schönfeld's formula in his second catalogue of variables, will attain a maximum by the same on July 8, and may therefore be observed as it approaches that phase. The next maximum takes place on April 1, 1882, and will not be observable.

χ Cygni, by the recent observations of Prof. Julius Schmidt, may also be expected to reach its maximum about July 10, perhaps a few days later: the last maximum occurred on May 30, 1880, when the star was 6m.; it has occasionally attained 4m. at maximum. The perturbations in this case appear to be considerable.

The position of the variable usually designated *Nova* 1848 may be identified by means of Prof. Schmidt's observations of neighbouring stars. In *Astron. Nach.*, No. 1708, he gives the following places for 1855·0:—

Mag.	R.A. h. m. s.	Decl. ° ′ ″	
11 ...	16 50 53·3 ...	−12 43 57	
13 ...	— 51 18·1 ...	12 42 0	
13·12 ...	— 51 22·5 ...	12 40 3	*Nova* 1848
11 ...	— 51 44·8 ...	12 47 8	
11 ...	— 51 51·9 ...	12 31 57	
10·11 ...	16 53 9·2 ...	−12 47 2	

Further, the variable follows the star, Lalande's star 30,853 a ninth magnitude, 14·8s., and is north of it 18′ 21″.

Prof. Winnecke's star of the twelfth magnitude, in close proximity to the place of Kepler's *Nova* 1604, deduced from the observations of Fabricius, and apparently in the position of a star marked 10m. by Chacornac, but not since observed of that brightness, well deserves watching, and it would be interesting to possess a carefully-formed map of all stars visible in the vicinity of Kepler's celebrated star, with the aid of one of our most powerful telescopes—similar to that prepared by D'Arrest with the Copenhagen refractor for the vicinity of Tycho's *Nova* 1572 in Cassiopea. Prof. Winnecke's star precedes the 9m., No. 16872 in Oeltzen's Argelander 33°2s., and is 2′ north of it.

The Satellites of Saturn.—Observations of these satellites are still followed up at the Observatory of Toulouse, and M. Baillaud has communicated a series made about the last opposition of the planet to the Paris Academy of Sciences. Amongst them are a number of observations of *Mimas*, consisting mainly of elongations, but with several attempts to fix the moments when the satellite was on the tangent to the extremity of the ring. M. Baillaud does not appear to regard the latter observation with favour, on account of the difficulty attending it, but proposes to gain further experience of the degree of precision of which it admits. The later observations of *Mimas* are as follows:—

1880	h. m. s.	1880	h. m. s.
Nov. 1 ... W. ...	6 59 40	Nov. 25 ... N.E. ...	10 23 50
13 ... W. ...	12 58 17	Dec. 18 ... W. ...	10 1 7
23 ... E. ...	10 33 13	19 ... W. ...	8 42 33

The times are mean times at Toulouse, 3m. 29·9s. west of the Observatory of Paris. The observation of November 25 relates to the passage of the satellite by the tangent to the extremity of the ring.

Dr. M. W. Meyer of Geneva publishes elements of *Enceladus*, *Tethys*, *Dione* and *Rhea*, obtained on a new method, from observations made with the 10-inch Geneva refractor. By the way he terms the second of these satellites *Thetis*, not the only time that Sir John Herschel's proposed designation has been mistaken of late. *Thetis*, as is well known, is appropriated for one of the minor planets discovered by Dr. R. Luther.

Swift's Comet (1881 *a*).—M. Bigourdan has calculated the following elements of this comet, from the Dun Echt observation on May 2 and observations made at Paris on May 5 and 7:—

Perihelion passage 1881, May 21·0613, Paris M.T.

Longitude of perihelion	297 54 43	M. Eq.
,, ,, ascending node	119 24 5	1881·0
Inclination	81 40 56	
Log. distance in perihelion	9·75568	

Motion—direct.

Though observations will not be longer practicable in these latitudes the comet may perhaps be observed in the southern

hemisphere, it being understood that telegrams have been sent to the Cape and to Australia (by Lord Crawford) with this object. According to the above orbit, on July 9 the comet will have one-fifth of the intensity of light on the night of discovery. There is no close resemblance of elements to those of any comet previously calculated.

THE "ASTRONOMISCHE NACHRICHTEN."—It is announced that after the termination of the current volume, by authority of the Prussian Government a new arrangement for the management of this journal will take effect. It will be edited by Prof. A. Krueger, the director of the Observatory at Kiel, in co-operation with the president of the "Astronomische Gesellschaft," of which association it will become a recognised organ.

BIOLOGICAL NOTES

LIMULUS POLYPHEMUS.—A paper on the anatomy, histology, and embryology of *Limulus polyphemus*, by A. S. Packard, jun., M.D. (*Anniversary Mem.* Boston Soc. Nat. Hist. 1880), may be regarded as a continuation of the author's former series on the development and affinities of the king-crab. He discusses fully the question of the affinities of that puzzling animal, and combating the position of those zoologists who connect Limulus with the Arachnida, he sums up the facts which point to the crustacean nature of Limulus as follows:—(1) The nature of the branchiæ, those of Limulus being developed in numerous plates overlapping each other on the second abdominal limbs (those of the Eutrypterida being, according to H. Woodward, attached side by side like the teeth of a rake), while the mode of respiration is truly crustacean; (2) the resemblance of the cephalothorax of Limulus to that of Apus; (3) the general resemblance of the gnathopods to the feet of Nauplius or larva of the cirrhipedia and copepoda; (4) the digestive tract is homologous throughout with that of Crustacea, particularly the Decapoda, there being no urinary tubes as in Tracheata; (5) the heart is on the crustacean type as much as on the tracheate type, and the internal reproductive organs (ovaries and testes) open externally, at the base of and in the limbs, much as in Crustacea. The paper is illustrated by seven plates showing the circulation of Limulus, sections of the adult and of embryos, and details of the structure of the eyes with comparison of these with those of Trilobites, with which group the author, as in his first memoir, allies the Merostomata.

THE NUMMULITIC ECHINIDS OF EGYPT.—A monograph of the Echinids contained in the Nummulitic strata of Egypt, by M. P. de Loriol, is published in the *Mem.* Soc. Phys. et d'Hist. Nat. de Genève (tom. xxvii. 1880, 1ere pe.). The specimens described by M. de Loriol were obtained mostly near Cairo and Thebes. The fauna of the Nummulitic strata of Egypt has been found by him as far as yet explored to contain forty-two species of Echinids, or about the same number as that of the Nummulitic strata of India; that of the Canton of Schwytz has only thirty-four, the Eocene fauna of the Antilles only eighteen; but the Eocene fauna of the Pyrenees has as many as ninety-three. In the present memoir, which is illustrated by ten plates, twenty new species are described. The author does not concur in Prof. Jeffrey Bell's reasons for the formation of his new genus Paleolampas, considering that there are not sufficient grounds for separating it from Echinolampas. Only four of the forty-two species composing the Egyptian Nummulitic fauna are regular Echinids, all the rest are irregular. Of the whole number all but eight are peculiar to Egypt. Of the eight exceptions four occur in the lower part of the Nummulitic formation at San Giovanni Harione, in the Vicentin, three in that of the Pyrenees, whilst the remaining one, *Hemispatangus depressus*, has been found in the Crimea in the same beds as *Echinolampas subcylindricus*, which also occurs at San Giovanni Harione.

SPONGES OF LAKE BAIKAL.—In a recent note to the St. Petersburg Academy, Dr. Dybowski says sponges occur in Lake Baikal wherever the bottom is rocky or large blocks of stone or wood are lying about. Close to the border of the lake, at a depth of 2 to 6 metres, they have a sod or cushion-like form, clinging to the stones, blocks, and (more largely) to decaying wood. In a depth of 6 to 25 metres they become tree- or shrub-like, with a height rarely exceeding 60 ctm.; while from 25 to 100 m. depth the sod or cushion-like form recurs, and only that is met with. The colour of the sponges is generally more or less dark grass-green, sometimes olive-green or brown. But those got from depths of 60 to 100 m., or found under stones, are nearly quite white.

MICROSCOPICAL EXAMINATION OF FARINA.—In examining any given kind of farina with the microscope to find whether a less nutritive farina has been mixed with it, it has been common to confine attention to the starch granules (which one may easily be mistaken about): Dr. Cattaneo holds (*Re. Ist. Lomb. Rend.* vol. xiv. fasc. v.) that greater importance should be attached to the character of the bran-particles, some of which are never wanting even in the most carefully-bolted flour. These (as he shows) differ in a marked way according to species.

THE HYPOPHYSIS IN ASCIDIANS.—While the hypophysis, or pituitary gland, found in the cranial cavity of adult vertebrates seems to be a rudimentary body without function, it is, in its earlier development, furnished, like all active glands, with an excretory passage into the alimentary canal. On the instance of M. van Beneden, M. Julin has lately studied an enigmatical organ in ascidians, a glandular apparatus under the brain (discovered by Hankow), which, it was thought, might be homologous with the pituitary gland of vertebrates. M. Julin examined the gland, the so-called anterior tubercle or vibratile organ, and various connected organs, in four species of ascidians at Leewik, on the Norwegian coast, and his researches (lately described to the Belgian Academy) appear to confirm M. van Beneden's conjecture. M. Julin is unable to regard the vibratile organ as an olfactory organ (the ordinary view); it receives no nerve-branch, and no olfactory cells can be found in its vibratile cylindrical epithelium. It is (he considers) merely the enlarged mouth of the excretory canal of the gland below the brain, leading into the buccal region, while the gland itself represents, in permanent state and functional activity, the embryonic hypophysis which becomes rudimentary in vertebrates. The *rôle* of the gland remains in obscurity. (Anatomical details will be found in the Academy's *Bulletin*, No. 2.)

PHYSICAL NOTES

AN extremely ingenious explanation of the peculiar green phosphorescence observed by Crookes in his researches on high vacua has recently been given by Mr. J. J. Thomson of Cambridge. This phosphorescence appears on the inner surfaces of the exhausted glass tubes whenever they are exposed to the so-called molecular bombardment of particles projected from the negative electrode. Mr. Thomson points out firstly that, as predicted by Clerk-Maxwell and verified by Rowland, a moving electrified particle acts as a current of electricity and possesses an (electro-magnetic) vector-potential. Now where such an electrified particle strikes a glass surface and rebounds, its change of velocity is accompanied by a change of vector-potential, and the glass against which it impinges and rebounds will be subjected to a rapid change in electromotive force. But by Clerk-Maxwell's electro-magnetic theory of light this is precisely what happens when a ray of light falls upon it. And therefore it phosphoresces as it would under the impact of an actual ray of light. It would be interesting to inquire whether all phosphorescent and fluorescent phenomena are capable of an analogous explanation in accordance with Clerk-Maxwell's theory.

MR. E. H. COOK proposes (*Phil. Mag.*) the term *sonorescence* as suitable to apply to the phenomena discovered by Graham Bell and investigated by Mercadier, Tyndall, and others, of the direct conversion of intermittent radiations into sound. The new name is obviously suggested by analogy with fluorescence and calorescence, but does not seem quite a happy one. Stokes gave the name of *fluorescence* to the phenomenon of the change of non-luminous ultra-violet rays into luminous ones. Akin gave the name of *calcescence* to the phenomenon of the change of non-luminous heat-rays into luminous ones (as in the lime-light), but the term has been superseded by Tyndall's term *calorescence*, which is etymologically unfortunate, seeing that the Latin verb is *calesco*, not *caloresco*. By strict analogy the term *sonorescence* should mean the conversion of sound into luminous rays, not the reverse change, to which Mr. Cook applies it.

THE researches of Edlund, Joubert, and others have left no doubt that the voltaic arc possesses an electromotive force of its own acting in a direction opposite to that of the current which sustains the arc. The principal work of maintaining the arc appears indeed to be spent in overcoming this opposing force, and is not occasioned by the resistance of the arc itself, which is small. M. Alfred Niaudet has lately announced the observation

of an important fact in connection with this subject, namely, that when the arc begins to emit the well-known *hissing sound* there is an abrupt change in the opposing electromotive force, which is greater while the arc is silent than when it is hissing.

MM. NACCARI AND PAGLIANI have lately determined the vapour tensions of a number of liquids in the laboratory of the University of Turin. Their method consisted of a modification of that of Regnault, reduction of pressure being effected by an aspirating pump. The tensions of toluene, propylic and isobutylic alcohol, and of several of the ethers of the fatty acids were determined at different temperatures with great exactitude and their empirical formulæ calculated.

FROM a study of the electromotive force of inconstant couples MM. Naccari and Guglielmo conclude that in couples containing one fluid the electromotive force is influenced by the nature of that pole to which the hydrogen goes, and that the change in the strength of the current varies always in the opposite sense to that of the electromotive force, the sense depending upon the manner in which the liberated oxygen enters into secondary chemical actions.

AT the Observatory of Campidoglio, Prof. Respighi has been lately conducting a series of experiments for the determination of gravity. The data are not as yet fully reduced, but the author has described his method (*Atti della R. Acc. dei Lincei*, vol. v. fasc. 5), which consists in the use of a pendulum with a lead ball about 9½ kg. in weight, and a steel wire 0·6 mm. in diameter; a sharp iron point at the extremity, dips in mercury each oscillation, so as to give passage to the current of a chronograph. Five different lengths of pendulum were used, between 7·90 m. and 5·16 m.; and with all these lengths the pendulum, on account of its weight, the fineness of the wire, and the convenient mode of suspension, proved independent of the rotatory motion of the earth, presenting Foucault's well-known phenomenon (an essential condition, in the author's opinion, but not verified in Borda's or Bessel's apparatus). The number and duration of the oscillations were registered by the chronograph with greater exactness than is attainable by the method of coincidences.

AN arrangement for rendering Volta's pile constant and depolarised is described by Count Mocenigo in a recent number of the *Rivista Scientifico-Industriale*. Twelve couples with their elements are fixed on a horizontal axis; a trough of acidulated water having twelve compartments is brought up by a lever motion, so as to cover a good third of the surface of the pile, and a rotatory movement is communicated to the axis.

THE velocity of sound in chlorine has been determined lately by Prof. Tito Martini (*Riv. Sci. Ind.*, No. 6), no physicist having previously, to his knowledge, done so. His method was suggested by an experiment of Tyndall. A glass tube 40 ctm. long and 2 ctm. internal diameter, and fixed in vertical position, was connected below, by means of a gutta-percha tube, to another glass tube holding sulphuric acid, and capable of being raised or lowered so as to vary the level of the liquid entering the fixed tube, in order to obtain the column of gas which would strengthen a certain tone. The fixed tube was graduated in centimetres and millimetres. Having first verified the accuracy of the method by experiments with carbonic acid and protoxide of nitrogen, the author proceeded to chlorine, and obtained 206·4 m. as mean value of the velocity of sound in it for zero temperature.

THE mode of decomposition of water by discharge of Leyden jars through platinum electrodes has been studied by Dr. Streintz (Vienna Acad. *Anz.*). Riess attributed this phenomena to heating of the electrodes. Using a quadrant-electrometer, &c., Dr. Streintz found that with very small electrodes giving passage to a series of discharge-currents in one direction, then left to themselves, a remarkable reversal of electromotive force occurred, but only when the discharges did not exceed a certain number. The author was led to examine the change of electromotive force by short galvanic currents, which also produce, in a few minutes, a reversal in the electric behaviour of the electrode covered with H_2; and he explains this by saying that platinum containing no free, but only occluded, hydrogen is electromotively negative to pure platinum. The further observation that a fully-polarised cell, one of whose electrodes was covered by a very brief galvanic current with H_2 the other with O_2, did not show a reversal of the difference of potential, led to the conclusion that the decomposition through battery discharges is to be regarded as the product of a galvanic polarisation and a connected (thermal?) development of oxyhydrogen gas on the two electrodes.

IN a recent note to the Vienna Academy Prof. Reitlinger and Dr. Wächter distinguish three varieties of Lichtenberg figures: (1) the positive radiating figure (*Strahlenfigur*); (2) the positive disk-figure; (3) the negative disk-figure. The (2) was lately added by Herr Holtz. The conditions of production in each case are investigated. The positive radiating figure is produced (according to the authors) by dust particles detached and carried off from the electrode; the negative disk-figure, on the other hand, by gas-discharges. In the former case the particles, while they communicate their positive electricity to the resin, describe radial paths rendered visible and yellow by the dusting process. The reason why one never gets a negative (red) radiating figure, or even branch, is that the electro-negative discharge from a metal or other conductor in air is neither capable of effecting an electric disaggregation of the electrode, nor a carrying away of dust-particles.

TO obtain an enlargement (on a screen) variable at will, at any distance, M. Crova (*Journ. de Phys.*, April) places between the object and the screen (which are fixed) a projection-apparatus formed of two lenses, one convergent (plane-convex), the other divergent (plane-concave), of the same focal distance, and capable of being moved apart by means of a rack and pinion arrangement.

GEOGRAPHICAL NOTES

MR. JAMES GLAISHER writes from the office of the Palestine Exploration Fund, announcing the discovery of a "Hittite" City.—"A great battle," he states, "figured in Sir G. Wilkinson's 'Ancient Egyptians,' was fought between Rameses II. and the Hittites near their sacred city of Kadash, which is shown as a city with a double moat, crossed by bridges beside a broad stream running into a lake. The lake has been generally identified with the Baheiret Homs, through which the Orontes passes south of Homs, but the site of the city, as important in Hittite records as the northern capital of Carchemish, remained to be discovered. We now learn from a despatch received from Lieut. Conder, the officer in charge of our new expedition, that he has identified the lost site with the ruins known as the Tell Neby Mendeh. They lie on the left bank of the Orontes, four English miles south of the lake. The modern name belongs to a sacred shrine on the highest part of the hill on which the ruins lie, and the name of Kadesh still survives, so that here is another instance of the vitality of the old names which linger in the minds of the people long after they have forgotten the Roman, Greek, or Crusaders' names. Not only the name is preserved, but the ancient moat of the city itself. Lieut. Conder writes:—'Looking down from the summit of the Tell we appeared to see the very double moat of the Egyptian picture, for while the stream of the Orontes is dammed up so as to form a small lake fifty yards across on the south-east of the site, a fresh brook flows in the west and north to join the river, and an outer line of moat is formed by earthen banks, which flank a sort of aqueduct parallel with the main stream.'"

THE French Government is taking advantage of the occupation of a part of Tunis to extend their ordnance survey to regions hitherto untrodden by ordinary travellers. Col. Perrier, the member of the Institute who is at the head of the French Survey, has been ordered for this service.

THE death is announced of Gessi Pasha, the friend and coadjutor of Col. Gordon in the Sudan. He died on the evening of April 30, in the French hospital at Suez, after protracted sufferings caused by the terrible privations he endured in the months of November and December last, when he was shut in by an impassable barrier of weed in the Bahr-Gazelle River, Upper Egypt, as already recorded. Capt. Gessi conducted some valuable exploring work on the Nile under Col. Gordon, and in 1876 succeeded in circumnavigating Albert Nyanza, adding greatly to our knowledge of that lake.

IN the *Revue Scientifique* of May 14 M. G. Rolland has a long article on the Sand Dunes of the Sahara, in which he adduces data to show that these dunes shift but very little, that although they move towards the south-east, it is very slowly, and that little difference is made upon them in the course of a generation.

"CAMEOS from the Silver-Land," by Mr. E. W. White, F.Z.S., will shortly be issued in two volumes by Mr. Van Voorst. It relates to the author's experience in the Argentine Republic, and will be specially full on the natural history of the country.

WE regret to learn the death of Admiral La Roncière le Noury, president of the Geographical Society of Paris, who died on Saturday after a protracted illness. He was born in 1813. In 1856 he went to the Arctic Ocean in the *Reine Hortense* on a scientific exploration professedly conducted by Prince Napoleon, who was on board. On the death of M. Chasseloup Laubat the Admiral was elected president of the Paris Society of Geography, in which office he continued without opposition up to the last election. The Admiral took great interest in scientific geography, as well as in zoology and botany.

DR. GERHARD ROHLFS, who has been travelling in Abyssinia, has returned to Berlin.

THE HYPOPHYSAL GLAND IN ASCIDIANS

SINCE the publication of Kowalewsky's remarkable discovery of the course of development in Ascidians, and its confirmation, in all the leading features, by Kupffer and others, any morphological work on the Tunicata is naturally regarded with great interest on account of the possibility of its throwing light on the difficult problem of the relationship of that group to the Vertebrata.

Embryological investigations have clearly demonstrated that the fully-formed larval Ascidian (in most genera, at least) possesses an axis occupying the centre of the tail, and comparable with the vertebrate notochord; that the dorsal region of the body contains a neural canal—of epiblastic origin, and formed by the rising up, arching over, and coalescence of "laminæ dorsales"—expanding anteriorly as a vesicle, in the walls of which certain sense-organs are developed, and being continued posteriorly as a fine canal running along the tail on the dorsal surface of the notochord. The ventral region of the body is occupied by the alimentary canal, lying below the nerve vesicle, and, in its most posterior prolongation, below the anterior extremity of the notochord, which in this locality separates the neural and visceral canals. These developmental researches have also shown that in the adult Ascidian the branchial aperture must be regarded as homologous with the vertebrate mouth, and the branchial sac with the pharynx.

An excellent paper by M. Charles Julin[1] in the last number of the *Archives de Biologie* (tome ii. fascicule i, 1881), of which a preliminary account appeared lately in the *Bulletin* of the Académie Royale de Belgique (3me ser., t. 1, No. 2, Fevr. 1881), adds to this interesting list of homologous organs by showing strong grounds for the belief that the little-understood "neural gland" in the Ascidians represents the glandular portion of the hypophysis cerebri, or pituitary body of Vertebrates.

M. Julin gives a minute account of the structure and relations of the peripharyngeal bands, the dorsal lamina, the nerve ganglion, and that enigmatical organ generally known as the olfactory tubercle; the most important section of his paper, however, is that dealing with the neural gland. This structure was first discovered by Hancock, and more recently its glandular nature was demonstrated by Ussow, who called it the olfactory gland, and stated that it was connected with the olfactory tubercle by a narrow canal, an observation since confirmed by Nassonoff. Julin contends that the so-called olfactory tubercle is not a sense-organ at all, but merely the curiously complicated opening into the pharynx of the duct of his "hypophysis." He states that he has been unable to find any nervous connection whatever between the tubercle and the ganglion, and that the nerve which has frequently been observed and described as supplying the supposed sense-organ really passes behind it without communicating, and that therefore he cannot confirm the innervation described and figured by Ussow. The histological structure of the tubercle is also opposed to the probability of its sensory function, as no modified cells are present, the whole surface being covered by normal ciliated columnar epithelium.

The reasons which M. Julin advances in support of the homology of the neural gland with the pituitary body are its structure, its position on the ventral surface of the ganglion, and its relation with the pharynx. The glandular nature of this body was first shown by Ussow, and its minute structure has been investigated by Julin. It consists of branching glandular tubules surrounded by connective tissue richly supplied with blood-sinuses, while the excretory duct in its posterior part has a complete dorsal wall only, as ventrally it communicates freely with the ends of the tubules, just as is the case with the duct during the development of the pituitary body.

Julin points out that in the Ascidians the duct, in running anteriorly towards the olfactory tubercle, is in direct relation with the ventral surface of the nerve ganglion, no layer of connective tissue intervening; and this he states is also the case in Vertebrates.

The position of the neural gland, or "hypophysary gland," as Julin proposes it should be called, is constant. Wherever the nerve-ganglion may be,—and it varies considerably in its position in different species,—the gland is always situated on its ventral surface.

The excretory duct arising from the dorsal surface of the gland, runs anteriorly, directly below the nerve-ganglion, to the olfactory or hypophysary tubercle, where it communicates with the pharynx, probably within the region formed by the epiblast involved in the oral invagination.

It is evident that Julin's observations throw the gravest doubts on the always somewhat questionable olfactory nature of the dorsal tubercle. A ciliated pit having no apparent nervous relations, and connected by a duct with a body having a well-marked glandular structure, has no claim to be regarded as a sense organ. Its function, and that of the gland, remain a mystery; Julin states that he is unable to throw any light upon this question. From the large size of the gland and the constant presence and usually extraordinary complication of the tubercle one would imagine that they performed an important function in the economy of the Ascidian; but what that function is, and why the duct of a gland should have so elaborate an opening into the pharynx, are at present totally unknown.

Julin gives us no information as to the development of these organs. In 1871 Kowalewsky[1] described, in the course of the development of *Ascidia mammillata*, the formation of an aperture connecting the anterior end of the nerve vesicle with the region of the epiblast which was being invaginated to form the oral funnel, and he declared that this aperture of communication between the neural and visceral canals persisted in the adult as the ciliated tubercle. Kupffer,[2] in the following year, while referring to Kowalewsky's statement, declared that he had been unable to discover any such aperture in the larva of *Ascidia mentula*. If Kowalewsky's observation is confirmed, and if the canal is found to remain as the duct of the neural gland, the course of its development would seem to differ considerably from that of the hypophysis cerebri as described by Mihalkovics, Balfour, and Kölliker, which are the views approved of by Julin and confirmed from his own observations.

In conclusion, the arguments in favour of the homology of the Ascidian's neural gland with the glandular portion of the pituitary body are very strong. The structure, position, and relations of the two organs are, in a certain stage of development, identical—admitting, of course, that the branchial sac is a modified pharynx, and that the nerve-ganglion is homologous with the vertebrate brain—and the only point required for the proof of the hypothesis is the demonstration that the neural gland and its duct are epiblastic in formation, and that their development corresponds with that of the pituitary body.

W. A. HERDMAN

[1] "Recherches sur l'Organisation des Ascidies simples—sur l'hypophyse et quelques organes qui s'y rattachent dans les genres *Corella*, *Phallusia*, et *Ascidia*. Par Charles Julin, Assistant du Cours d'Embryologie à l'Université de Liège.

STORING OF ELECTRICITY

SECONDARY batteries to store up currents of electricity in the form of chemical work promise to play so important a part in the ultimate adoption of the electric light, that improvements in their construction are of peculiar interest. The latest innovation is due to M. Faure, who has modified with great success the secondary battery of Gaston Planté by covering the surfaces of the lead plates with a coating of minium, thereby increasing their capacity manifold. This device possesses the additional advantage that it obviates the necessity of "forming" the cells by the tedious process of charging and discharging them for many days, as in Planté's batteries. Two sheets of lead are separately coated with minium and are rolled together in a spiral, being kept apart by a layer of felt, and are then placed in a

[1] "Weitere Studien über die Entwicklung der einfachen Ascidien" (*Arch. f. microsc. Anat.*, vol. vii.).

[2] "Zur Entwickelung der einfachen Ascidien" (*Arch. f. microsc. Anat.*, vol. viii. 1872).

vessel containing dilute acid. When a current is passed into this cell the minium on one plate is reduced to metallic lead that on the other is oxidised to the state of peroxide. These actions are reversed while the charged cell is discharging itself. According to M. Reynier one of these cells made large enough to weigh 75 kilograms may store up energy sufficient to furnish afterwards one-horse power of work for an hour.

A correspondent of the *Times* of Monday gave an interesting account of an experiment he witnessed in Paris of storing electrical energy by the method adopted by M. Faure.

"A Faure battery, or *pile secondaire*," he states, "was charged with the electric fluid direct from the ordinary Grove battery and in my presence. It may be more economically done from a Gramme or Siemens machine. The receptacle consisted of four Faure batteries, each about five inches diameter and ten inches high, forming a cylindrical leaden vessel, and containing alternate sheets of metallic lead and minium wrapped in felt and rolled into a spiral wetted with acidulated water, and the whole placed in a square wooden box measuring about one cubic foot and weighing some seventy-five pounds. This was protected by a loose wooden cover, through which the electrodes (in lead) protruded, and were flattened down for convenience of transport. This box of 'electric energy' was handed to me by M. Faure at my request, with the object of submitting it for examination and measurement to our eminent electrician, Sir William Thomson, F.R.S., at the University of Glasgow. I had the box by me all through the journey from Paris on Tuesday night (last week), including a five hours' delay at Calais. I arrived at Charing Cross at 11 a.m. on Wednesday, after running the gauntlet of customs and police authorities, who suspiciously looked askance and seemed to doubt my statement that my box only held 'condensed lightning,' and contained no infernal machine or new explosive destined to illustrate some diabolical socialistic tragedy. From time to time on the journey I tested the force of the discharge and found it to have well maintained its energy. From London to Glasgow required only another ten hours, and finally, in about seventy-two hours from the time of charging in Paris, I had the satisfaction of presenting to Sir William Thomson M. Faure's rare offering of a 'box of electricity,' intact and potent, holding by measurement within that small space of one cubic foot a power equivalent to nearly one million of foot pounds! This wonderful box is now deposited in the laboratory of the Glasgow University, under the vigilant eye of its director, and being submitted to a series of tests and measurements, the results of some of which made Sir William exclaim, 'Why, it's a little witch.'" With reference to this Sir Wm. Thomson writes to us under date May 17:—"I had the marvellous box under trial for seventy-two hours before I left Glasgow yesterday, giving it successive charges, and discharging to various degrees, measuring approximately the whole quantity sent in during the charge, and taken out in the discharge. Thus I shall be able to calculate the amount of energy spent, and the amount recovered under various conditions. Mr. J. T. Bottomley continues the trials in my absence. A considerable time must pass before I have results to publish."

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The report of the Botanic Garden Syndicate, as it now stands, recommends the admission of members of the Senate into the Garden on Sunday afternoons from three to six during the present summer, and as an experiment only; three friends may be introduced at the same time, their names being written in a book. Only one entrance is required to be opened, and the curator or his deputy and one policeman are to be present. The number of signatures of residents in favour of this change is very large. Prof. Babington object-, and so do the heads of Queen's, Pembroke, and St. Catherine's Colleges, Professors Cowell and Westcott, and several resident clergymen.

At Trinity College W. R. Sorley (second year) has been elected to a Foundation scholarship for Moral Science, and D'Arcy Thompson (first year) to a Scholarship for Natural Science; E. D. Ritchie (Winchester) and W. B. Ransom (Cheltenham) to Exhibitions of 40*l.* for Natural Science. At King's College S. F. Harmer has been awarded the Vintner Exhibition for Natural Science, and A. P. Laurie (Edinburgh Academy) an Exhibition of 50*l.* for two years.

Mr. Lea is lecturing, in Dr. Foster's advanced course, on the Physiology of Vision.

Mr. Hicks is taking an examination class in Elementary Botany at Sidney College.

Dr. Vines' course of botany this term is one of Morphology, chiefly cryptogamic, with practical work.

The first M.B. Examination commences on June 13, the second on June 7, the third on May 10; the M.C. Examination on June 13.

The open mathematical lectures this term are those of Mr. Dale (Trinity) on Heat, and Mr. Taylor on Higher Plane Curves, Mr. Besant (St. John's), on Sound and Vibrations, Mr. Webb (Emmanuel) on the Potential and Green's Theorem, and Mr. Temperley on Finite Differences.

The first part of the Natural Sciences Tripos begins on June 6.

IN the report of the last Local Examinations (December, 1880) it is stated that the juniors answered satisfactorily in Botany, while the descriptions of specimens by the seniors and their answers in Vegetable Physiology were very weak. In Zoology the seniors did better relatively than the juniors, but practical work was largely deficient. In Geology the answering was bad, and the practical knowledge of specimens extremely meagre.

LONDON.—At the presentation day last week at the University of London, when the certificates of degrees and honours won by the successful students at the late examinations were distributed, three ladies received certificates of matriculation, and four degrees of B.A. Earl Granville said that this year they had lost by death Sir Philip Egerton, a man of great cultivation, who had always shown the greatest interest in the work of the University. There were other losses which they regretted, but which carried some consolation with them, as being highly to the credit of the University—as, for instance, the departure of Dr. Greenfield, who had for so long been identified with the Brown Institution, to Edinburgh University. They were perhaps aware that in 1852 Mr. Brown had left a sum exceeding 20,000*l.* for the creation of an institution for the investigation and cure of diseases peculiar to animals useful to man, the donor expressing a desire that the University of London should appoint a committee of their body or of medical men outside to scientifically carry out his views. Ten years ago that institution was established, and during that period few or no cases of interest to it had been discussed in which it had not taken a leading part. These investigations had, he believed, been carried on in a manner which promised the greatest possible advantage, not only with regard to the diseases of animals, but also to those of man. During the past year 3870 animals had been cured, and as an example of the great kindness with which the patients were treated he would relate the following anecdote:—A distinguished member of the Senate was driving along the road in which the institution was situated when suddenly his hack cab came to a dead stop. He asked the driver whether his animal was lame or ill, but the driver answered, "No sir. I never can get him past this place since he had his corn cured here; he likes it so much that he always wants to stop." Results had shown that the University was justified in extending the limits of its operations to the Brown Institution. After careful consideration it had been determined to extend the examinations into the science and art of teaching, for which purpose a scheme had been prepared, which would shortly be carried out. As a member of a Government which adopted as its first principle economy of public funds he was glad to be able to give an instance that this did not always degenerate into niggardly stinginess. Their application to the Treasury for the establishment of a practical museum of natural history to enable them satisfactorily to carry on examinations on their own premises had been most liberally met, and he hoped that in a very short time such a department would be opened.

THE annual distribution of prizes to the successful students at the London School of Medicine for Women took place on Wednesday last week. The report stated that up to the present eighty-six pupils had been received, of whom forty-four are now attending. Nine of these were studying for the University of London, four were amateurs, and the remaining thirty-one were training for examination by the College of Physicians in Ireland. Altogther twenty-five ladies had now been declared qualified to practise. The report of the treasurer, the Right Hon. James Stansfeld, M.P., stated that the expenditure had been 2018*l.*, of which one-half had been provided by the students' fees. The subscriptions had been 626*l.* 17*s.* 6*d.*, as against 723*l.* 15*s.* 6*d.*

last year; and the donations 33*l.* 2*s.*, as against 18*l.* There had been several large legacies realised, amongst them one of 4050*l.* from Mrs. George Oakes.

MANCHESTER.—We understand that a sum of 1500*l.* has been offered by a benefactor to the Council of Owens College for five fellowships of 100*l.* a year, each renewable for a second or third year, the conditions being that they shall be awarded on evidence given by the candidates of their past work in literature or science, and on their satisfying the electors as to their subsequent devotion to original work. The scheme is as yet only under consideration. We likewise understand that Mr. Waterhouse is preparing plans for completing a portion of the buildings required for Owens College, including museums for natural history, geology, and mineralogy, and for the lecture-rooms and laboratories required for the professors of the above subjects.

On Saturday next (May 21) Prof. Boyd Dawkins, F.R.S., will begin the seventh series of Field Lectures in Geology, at Miller's Dale Station, Derbyshire. That and the two following Saturdays will be devoted to the examination of the Carboniferous rocks of the Pennine Chain. On Saturday, June 9, the class will visit the British Museum (natural history) under the guidance of Dr. Woodward, F.R.S., for the study of the mammalia associated with Pleistocene Man. On June 10 the brickfields at Crayford and Erith, in Kent, will be visited under the guidance of Mr. F. C. Spurrell; and on the 11th the subject of the Antiquity of Man will be finished by an examination of the collections of prehistoric archæology in the British Museum (Bloomsbury).

THE Queen has directed letters patent to be passed under the Great Seal granting and declaring that the degrees of Bachelor and Master of Arts and Bachelor and Doctor of Medicine, of Laws, of Science, and of Music, granted or conferred by the University of Adelaide, South Australia, on any person, male or female, shall be recognised as academic distinctions and rewards of merit, and be entitled to rank, precedence, and consideration in the United Kingdom and in the colonies and possessions of the Crown throughout the world, as fully as if the said degrees had been granted by any university of the United Kingdom.

SCIENTIFIC SERIALS

Journal of the Royal Microscopical Society for April, 1881, vol. i. ser. ii. part 2, contains—Prof. P. Martin Duncan, on a Radiolarian and some Microspongidæ from considerable depths in the Atlantic Ocean (plate 3).—Dr. Lionel S. Beale, the President's address.—Prof. E. Abbe, on the conditions of orthoscopic and pseudoscopic effects on the binocular microscope.—A. D. Michael, on a species of Acarus believed to be unrecorded (plate 4).—Prof. E. Abbe, on the estimation of aperture in the microscope. The summary of current researches, pp. 217–364.—Proceedings of the Society. (In the summary of current researches appears a memoir by Mr. Crisp, "On Aperture, Microscopical Vision, and the Value of Wide-Angled Immersion Objectives," in which the whole subject is very exhaustively and clearly put.)

Annalen der Physik und Chemie, No. 4.—Experimental investigation of the connection between refraction and absorption of light, by E. Ketteler.—On the ratio of intensity of the two sodium lines, by W. Dietrich.—On the condensation of gases on surfaces in their relation to pressure and temperature, by H. Kayser.—Influence of pressure on the surface-tension of liquids, by A. SOCIETIES AND ACADEMIES

LONDON

Royal Society, April 28.—"The influence of Stress and Strain on the Action of Physical Forces." By Herbert Tomlinson, B.A. Communicated by Prof. W. Grylls Adams, M.A., F.R.S. Part I.—Elasticity. "Young's Modulus."

The values of "Young's modulus" were determined for several metals by a method devised by Sir W. Thomson.

A large number of experiments with different loads were made, and after a great many unsuccessful attempts to account for certain discrepancies which could not be explained away as errors of observation, the following facts were elicited :—

1. After a wire has suffered permanent extension, the temporary elongation which can be produced by any load becomes less as the interval between the period of permanent extension and that of applying the load becomes greater.

2. This increase of elasticity is greater in proportion for large loads than for small ones.

3. The increase of elasticity takes place whether the wire be allowed to remain loaded or unloaded between the period of permanent extension and that of the testing for the elasticity.

4. The *rate of increase* of elasticity varies considerably with different metals; with some the maximum elasticity is apparently attained in a few minutes, and with others not till some days have elapsed, iron and steel being in this last respect very remarkable.

5. The elasticity can also be increased by heavily loading and unloading several times, the rate of increase diminishing with each loading and unloading.

6. A departure from "Hooke's law" more or less decided always attends recent permanent extension, even when the weights employed to test the elasticity do not exceed one-tenth of the breaking weight.

7. This departure is diminished very noticeably in the case of iron, and much less so in the case of other metals, by allowing the wire to rest for some time either loaded or unloaded; it is also diminished by repeated loading and unloading.

The effect of permanent extension on the value of "Young's modulus" was tried according to the direct method for iron and copper, and indirectly for most of the metals.

From both the direct and indirect methods results were obtained which showed :—

1. That, in all metals, provided the wire has not been kept heavily loaded for some time before testing, permanent extension produces decrease of elasticity, if the strain be not carried beyond a certain limit.

2. That, if the extension be carried beyond the above-mentioned limit, further permanent increase of length causes increase of elasticity.

3. That, in the case of iron, heavy loading for some time so increases the elasticity that, even when the extension would have caused diminution of elasticity without such continued loading, the latter will, if sufficient time be allowed, change this diminution into an increase; in the case of copper this is not so.

The effect of suddenly chilling steel heated to a high tempera-

ture was found to be similar to that of excessive permanent extension of iron.

Several experiments were made to test the effect of permanent torsion and permanent extension on the modulus of rigidity.

From these experiments it was concluded :—

1. That the loss of rigidity produced by twisting or stretching a wire beyond the limits of elasticity is partly diminished by rest.

2. That the loss is more sensible with large arcs of vibration than with small ones.

3. That the influence of rest is more apparent in the case of large vibrations than in that of small ones.

4. That continual vibrating through large arcs has a similar effect on the rigidity to that produced on the longitudinal elasticity by heavily loading and unloading. And—

5. That in the case of hard steel the effect of vibrating through a large arc for several minutes makes temporarily the rigidity as determined from such vibrations greater than that determined from smaller vibrations.

The influence of an electric current and of magnetism on the torsional rigidity of metals was also investigated, and the following results arrived at :—

1. The torsional rigidity of copper and iron is temporarily decreased by the passage of a powerful electric current, but is very little, if at all appreciably, altered by currents of moderate intensity.

2. The torsional rigidity of iron is temporarily diminished to a small but perceptible extent by a high magnetising force.

3. The effects mentioned in 1 and 2 are independent of any changes produced by the current in the temperature of the wire.

Finally, certain critical points are alluded to, there being at least two such for each metal, at which sudden changes take place in the ratio of the permanent extension produced by any load and the load itself.

May 5.—"On the Structure and Development of the Skull in Sturgeons (*Acipenser ruthenus* and *A. sturio*)," by W. K. Parker, F.R.S.

I must refer the reader to Prof. Salensky's[1] invaluable work on the development of the sterlet (Kasan, 1878), unfortunately published in *Russian*, and to the second volume of Mr. Balfour's new work, for an account of the earliest stages of the *Acipenserine* embryo.

Even in larvæ one-third of an inch in length, the cartilage was becoming consolidated, and I was able to work out, by sections and dissections, the structure of the cranium and visceral arches; the one specimen which was seven-twelfths of an inch in length, and which was made into a large number of extremely thin sections, left nothing to be desired.

The development of the skull of the sturgeon is very similar to what we find in the sharks and skates ("Selachians"), but the suspension of both the mandibular and the hyoid arches by one pier, derived from the hyoid (the *hyostylic* skull), which is seen in the Selachians on one hand and in the Holostean Ganoids and Teleosteans on the other, attains its fullest development in the "Acipenseridæ," or Chondrosteous Ganoids; for in them the "symplectic" is a separate cartilage, and not a mere osseous centre as in *Lepidosteus* and the Teleostei.

Here I find a very noticeable fact, namely, that whilst in the salmon the metamorphosis of the simple primary arches of the face can be followed step by step, in the sturgeon the peculiar modification of the arches shows itself *during chondrification*; the hyoid arch, from the first, is inordinately large.

Notwithstanding the huge size of the sub-divided hyoid pier, its head only articulates in the larva with the auditory capsule; later on the basal cartilage reaches it, as in the Selachians.

But the arches that retain their normal size lend no colour to the theory that the visceral arches are related by their dorsal ends to the paired cartilages that invest the notochord, a state of things like that seen in the ribs and in the superficial cartilaginous hoops that surround the huge pharynx of the lamprey.

Mr. Balfour has demonstratively shown that in the branchial region, when the pleuro-peritoneal cavity has been sub-divided by the hypoblastic outgrowths of the pharynx, the aortic arches lie *inside* the small temporary "head cavities," or remnants of the once continuous sub-division of the body wall into an inner layer, the "splanchno-pleure," and an outer layer, the "somato-pleure."

But the aortic arches mount up, on each side, *outside* the proper branchial arches, which become grooved to receive them; these arches must therefore be considered as developments of the temporarily separate "splanchno-pleure"; they cannot be classed with the *costal* arches, which are developed in the permanently distinct "somato-pleure."

My dissections and sections, both of this type and of the Selachians, show, without leaving room for doubt, that all the visceral, or, properly speaking, *branchial* arches, mandibular, hyoid, and post-hyoid (branchial proper) are developed in the outer walls of the large respiratory pharynx, quite independently of the base of the skull and the fore part of the spinal column.

I have at last ceased to contend for true branchial or visceral arches in front of the mouth, and also to look upon the mouth and the openings around or in front of it as more than mere *involutions* of the epiblast; the *first cleft* is that between the mandible and the hyoid arch, the first arch is the mandibular.

With regard to the skull, it is now very evident that the "trabeculæ cranii," even in their furthest growth forwards from the end of the cephalic notochord, are merely *foregrowths* from the moieties of the investing mass (the parachordals), the true axis of the cranial skeleton ending under the fold of the mid-brain. The "cornua trabeculæ," and the "intertrabecular" part or tract, are *fresh shoots*, so to speak of cartilage that are specially developed to finish the cranial box and the internasal framework. I fear that my long-cherished *pre-oral visceral arches* will now have to go down and take their place among these *secondary* or *adaptive* growths.

I may remark, in concluding this very imperfect "abstract," that the sturgeon is a very important type for the morphologist to get clear light upon.

In the Selachians the huge pterygoid foregrowth of the mandibular arch aborts the apex of its pier, whose *function* is supplied by the hyo-mandibular; fragments only are developed in its upper part.

In the sharks from *one* to *three* mere "rays" are developed in front of the small upper remnant of the first cleft ("spiracle"); in skates there is, as a rule, a small separate piece, the true apex of the arch, its "pedicle." In one kind, however, the torpedo, four such fragments appear on each side, as shown by Gegenbaur. In the sturgeon there is a most remarkable plate in the common metapterygoid region, its form is rhomboidal; it is composed of a number of well-compacted pieces of cartilage, a middle series of *azygous* plates, and a somewhat irregular arrangement of plates right and left of these. This remarkable structure only exists in the Acipenseroids; it is not found in *Polyodon*.

In the Selachians the "placoid" plates or spines are not brought under the influence of the chondrocranium, which has neither parosteal plates applied as splints to it nor ectosteal plates grafted upon it.

In *Acipenser* there are both parostoses applied to the oral apparatus, and ectosteal centres in the post-mandibular arches; morever, along the side of the skull, in old individuals, plates of bone appear as splints or parostoses, that are manifestly the forerunners of the deeper plates that in the higher Ganoids and the Teleostei form the proper ectosteal bony centres of the more or less ossified cranial box.

The Ganoid scutes of the sturgeon are so far dominated by the huge chondrocranium, that *by courtesy* they may be called frontal, parietal, opercular, and the like; of course such scutes are not the accurate homologues of the bones so named in the Teleostei, which at the most can only correspond to the inner layer of the scute of such a fish as the sturgeon.

The sturgeons as a group cannot be said to lie directly between any one family of the Selachians and any one family of the Bony Ganoids, yet on the whole that is their position; the Bony Ganoids on the whole approach the Teleostei, especially such forms as *Lepidosteus* and *Amia*, which have lost their "spiracle," and in other things are less than typical, as Ganoids.

Larval sturgeons are, in appearance, miniature sharks; for a few weeks they have a similar mouth, and their lips and throat are beset with true teeth that are moulted before calcification has fairly set in. Their first gills are very long and exposed, but not nearly so long, or for such a time uncovered, as in the embryos of sharks and skates.

Mathematical Society, May 12.—S. Roberts, F.R.S., president, in the chair.—Prof. C. Niven, F.R.S., was admitted into the Society, and the following were elected members :—I. Rosenthal, B.A. Dublin, C. A. van Velzer, F. Franklin, Ph.D., and Miss Christine Ladd, the last three of the Johns Hopkins

[1] My smallest specimens were the gift of Prof. W. Salensky, the larger of the late Mr. William Lloyd.

University, Baltimore.—The following communications were made:—On Ptolemy's theorem, by Mr. Merrifield, F.R.S.—The summation of certain hypergeometric series, by the Rev. T. R. Terry.—Quaternion proof of Mr. S. Roberts's theorem of four co-intersecting spheres, by Mr. J. J. Walker.—Some solutions of the "15-girl" problem, by Mr. Carpmael.—Note on the co-ordinates of a tangent line to the curve of intersection of two quadrics, by Mr. W. R. W. Roberts.—Shorter communications were made by the President, Prof. Cayley, F.R.S., Mr. Hart, and Mr. J. J. Walker.

Entomological Society, May 4.—H. T. Stainton, F.R.S., president, in the chair.—Two new Members and one Subscriber were elected.—Mr. R. Trimen made some observations on the sexes of *Pieris saba*, *Diadema mima*, and *Papilio cenea*, and exhibited specimens in illustration. He also remarked on *Tinea gigantella* having been bred from the hoof of a dead horse, and on the uncertainty which still exists as to whether the larva of this species ever feeds on living horn or not.—The Secretary read a letter from the Colonial Office respecting the occurrence of *Phylloxera vastatrix* on vines in Victoria.—Mr. A. G. Butler communicated "Descriptions of New Genera and Species of Heterocarous *Lepidoptera* from Japan—*Noctuites*."

PARIS

Academy of Sciences, May 9.—M. Wurtz in the chair.—The following papers were read:—Reply to some criticisms of the note of February 21, on the parallax of the sun, by M. Faye. He invites his English critics to correct his ten numbers according to their best information, and expects they will reach nearly the same result.—On nitrate of diazobenzol, by MM. Berthelot and Vieille. This solid crystalline body ($C_{12}H_4N_2NO_6H$) detonates with extreme violence when heated above 90° (and is thus much more sensitive to heat than fulminate of mercury). It also detonates when struck with a hammer or rubbed. It is now much used in making colouring matters.—On a new derivative of nicotine obtained by the action of selenium on this substance, by MM. Cahours and Étard. The collidine obtained is one of the propylpyridines corresponding to the isomeric position, still unknown, of nicotianic acid. Theory anticipates six collidines of this species. Selenium is found to be capable of removing nitrogen from an organic substance.—On the divisors of functions of periods of primitive roots of unity, by Prof. Sylvester.—On the densities of liquefied oxygen, hydrogen, and nitrogen in presence of a liquid without chemical action on these simple substances, by MM. Cailletet and Hautefeuille. The mixture was chiefly with carbonic acid. The density varied considerably with temperature and pressure. The coefficients of dilatation are so little different that the densities must be sensibly in the same ratio at 0° and at −23°. The atomic volumes calculated are 17 for O, 30·3 for H, and 31·8 for N (dividing each of the atomic weights by the density at −23°, viz. O, 0·89, H, 0·033, and N, 0·44). Gaseous O, H, and N diverge very unequally from Mariotte's law, at the pressures employed (275 and 300 atm.), and there is not then a simple relation between the atomic weight and the density; but on change of state by lowering of temperature in presence of a gas easily liquefiable, the atomic volume is found to reveal a positive relation between density and equivalent weight.—M. de Gasparin was elected Correspondent in Rural Economy, in room of the late M. Kuhlmann.—On displacement of a figure of invariable form in its plane, by M. Dewulf.—On the work-product of secondary batteries, by M. Regnier.—M. Mascart stated that Admiral Cloué, Minister of the Marine, would probably organise an expedition to islands near Cape Horn, taking part in the international scheme of simultaneous observations on terrestrial magnetism, &c.—On seeds of two species of Chinese vines discovered in 1872 by Abbé David in the province of Chen-si, by M. Du Caillaud.—M. Vinot submitted a telescope made on a suggestion of M. Caussin. The image formed by one telescope is looked at with another of the same or different power.—Observations of Saturn's satellites at Toulouse in 1879 and 1880, by M. Baillaud.—Observations, elements, and ephemerides of the comet *a* 1881 (discovered by Mr. Lewis Swift on April 31), by M. Bigourdan.—On a system of differential equations, by M. Halphen.—On trilinear forms, by M. le Paige.—On some actinometric measurements made in the Alps in 1880, by M. Puiseux. The total radiation (that diffused by ground and sky as well as that direct from the sun) was found to be increased 0·10 at an altitude of 800 m. and 0·21 at 2100 m. At greater heights (3380 and 3251 m.) the numbers were much higher, but less easy of interpretation, because of snow and mist; the reduced figures were 1·25 and 1·24 (showing good agreement with the others). Phanerogamic plants are found up to 3900 m., and must accomplish all their phases in the three summer months at a temperature below that of a polar summer. Doubtless the intensity of radiation compensates.—Action of light on phosphorescent substances, by M. Clémandot. He notes the confirmation, by M. Yung of Geneva, of his views that the phenomenon is physical, and the vibratory influence strongest in the blue ray. M. Becquerel called attention to his own researches thirty years ago.—Action of light on bromide of silver, by M. Noel. *Ceteris paribus*, silver bromide retains longer the molecular modification impressed on it by the chemical spectrum, the greater its sensibility, and when this first modification disappears it seems to have recovered its initial sensibility.—Action of carbonic acid on baryta and strontium, by M. Raoult.—On the products of action of perchloride of phosphorus on acroleine, by M. van Romburgh.—On the nature of the troubles produced by cortical lesions of the brain, by M. Couty. He rejects the theory of localisations, both on anatomical and physiological grounds.—On the poisonous action of the juice of manioc, by M. de Lacerda. It is not great, and it seems to affect the central nervous system.—On the *rôle* of marine currents in geographical distribution of amphibian mammalia, particularly Otaria, by M. Trouessart. These animals seem to have radiated from Antarctic regions. Their course to the North Pacific, &c., corresponds remarkably with that of certain currents.—Movements of juices and various plant-organs referred to a single cause; variations of hydrostatic tension, by M. Barthélemy.

VIENNA

Imperial Academy of Sciences, May 12.—V. Burg in the chair.—The following papers were read:—C. Claus, on tomora and tomorella.—Prof. L. Ditscheiner, on searching for spots of interruption at insufficiently insulated circuits.—E. Sathey, on the phenomena of exsiccation and imbibition on the involucra of Cymareæ.—Dr. R. Maly, on yolk-pigments.—E. Weiss, on the comet discovered by Lewis Swift (Rochester, U.S.) on May 2, &c.—E. Weiss, on a new method of computation of the apparent anomaly in orbits of great excentricity.—Dr. Zd. Skraup, on cinchonidine and homocinchonidine.

Imperial Institute of Geology, May 3.—The following papers were read:—Prof. Cornel. Doelter, on the geological state of the Cape Verde Isles.—M. Vacek, exhibition of the geological map of Trieste.—Dr. L. Szaynocha, on the occurrence of petroleum at Sloboda Rungurska.—Dr. E. Hussak, on the inclusion of resinous matters in the pyerite porphyry of Steyrdorf.

THE EVOLUTION OF THE CRYPTOGAMS

L'Évolution du Règne Végétatale. Les Cryptogames. Par MM. Saporta et Marion. Bibliothèque Scientifique Internationale, xxxi. (1881.)

THIS exceedingly valuable contribution to the history of the evolution of the vegetable kingdom, to be followed by a second volume dealing with the Phanerogams, is fully illustrated by 85 figures.

It is almost superfluous to remark on the exceptional qualifications with which the authors enter upon the task, for they have already produced some of the ablest works, particularly upon fossil plants. Although much of the material they have had to deal with has not been more than usually satisfactory, their work has been singularly free from the arrogance of other writers on the subject of fossil plants, who pretend to a clairvoyance enabling them to determine unhesitatingly even fragments of leaves of extinct trees when every organ necessary for botanical determination is absent. When, as in the great majority of cases, subsequent discoveries prove these gentlemen to be wrong, we hear nothing from them, but when their guesses prove right, they are exceedingly jubilant.

At the outset the authors lay some stress on the fact that a less complex organisation does not necessarily imply relative antiquity. Circumstances exceptionally favourable to certain series of plants have forced their development to a state never afterwards surpassed, but which, on the contrary, has retrogressed by the elimination of hastily-developed or prematurely-adopted types. New series or new branches given off by the same series have constantly replaced, in all ages, the series or the branches which have died out or declined, and the vegetable kingdom, taken as a whole, has constantly progressed. The book, moreover, is not written for those who totally disbelieve in the principles of evolution, for no proof that it contains will convince them; but those who wish to understand the successive modifications that have led to the comparatively recent group of Angiosperms, will find it full of interest.

Commencing with the Protista, the authors lead us through the Protophytes to the Lower Metaphytes, which together constitute the artificial group of Cryptogams. These represent an elder branch of the vegetable kingdom, and lead, by perfectly natural transitions, to the Phanerogams, the younger branch, of which the latter offshoots appeared only at long posterior dates.

The origin of all plants is in protoplasm, and those of the Protista which are amorphous, yet possess the essential attributes of life, may well be thought to reproduce the probable characteristics of the earliest primordial plants. On the southern shores of France creatures several centimetres in length are dredged from depths of five to ten fathoms, whose substance is entirely penetrated with fine particles of the sea bottom. They would pass unnoticed did they not shift their position with extreme slowness and extend short prolongations. Placed in a glass of sea-water they attach themselves to the sides, and free themselves gradually of sand, when a slightly yellow hyaline jelly, absolutely deprived of nucleary elements, is disclosed. They are allied to the Protamœba, Protobathybius, and Pelobius, and from these starting points all the progressive stages of development are traced.

In certain organisms among the Protista the protoplasmic mass secretes a rigid envelope, and when, further, a portion of the protoplasm becomes converted into another substance, "chlorophyll," all the characters of vegetable life are realised. In the interior of these cells the protoplasm remains truly amœbous, and acts and is acted upon in precisely the same manner as in animal amœbæ, but this special substance chlorophyl gives rise to a whole series of new physiological functions, and its presence alone marks off animal from vegetable life. The only distinction that can be drawn between the two kingdoms is thus entirely due at the commencement to a transformation of part of the elementary protoplasm.

Leaving the Protista, the authors treat at some length the embryogeny and methods of reproduction of Protophytes, especially the Algæ, tracing these through the primitive and single-celled diatoms and desmids, with soft or hard envelopes containing protoplasm charged with chlorophyl, to the higher forms in which special organs are developed, as the Florideæ, Fucaceæ, &c., and the Characeæ. Setting aside the Fungi and Lichens as groups whose development has been arrested by parasitic habit, the authors proceed to consider the manner in which aquatic vegetation became first adapted to terrestrial life.

While the more highly organised and complex Algæ have preserved those aquatic habits necessitated by physiological functions, numerous species of Nostochineæ, Palmelleæ, and Vaucheria have quitted the water from time to time to vegetate in humid places on land. These furnish the earliest indication of adaptability to aërial life, and it is curious to find that this proceeds from lower forms of Algæ but slightly differentiated from each other morphologically, and not from the more completely evolutionised types. Some, with flat cellular fronds, such as Ulva, crept, it is supposed, face to the ground and became ancestors of the Hepaticæ. Others, more confervoid, produced a thallus whose growth, necessarily apical, became complex by simple vegetative multiplication. Foliary appendicles were given off, and a sort of plantlet with rootlets, stem, and leaves, all strictly cellular, came into existence, capable, like the Mosses at the present day, of agamous reproduction. In the earliest stage of growth of the Equisetaceæ, of Ferns, and of Ophioglosseæ, we see a similar primordial cellular plant, called a Prothallus, develop from the spore, and resembling in every respect the lower Algæ. This prothallus bears the sexual organs, and it may here be noticed that it is impossible to insist too strongly on the influence exercised by the act of reproduction on the differentiation of primordial plants.

In lowly developed types the act of reproduction arrests what may be termed their nutritive life. This act may be "precocious" or "tardy," the variations in the time of sexuality exerting a dominant influence on the morphologic differentiation of life. In the well-known case of the Axolotl the embryos of the same birth may either have well developed or only rudimentary sexual glands. In the former case the fry reproduce precociously before losing their branchiæ, while those which reproduce more

tardily become transformed into "Amblystomes," their morphologic differentiation being unchecked by the act of reproduction. Similarly among primitive terrestrial Algæ, those in which sexuality was deferred until late had a longer period of purely vegetative life, and therefore not only felt more strongly the influence of new conditions, but had a longer time in which to adapt themselves and thus become diversified in type. The resultants of this elaboration are represented now by the Mosses and Hepaticæ. In the Mosses the spore gives birth to a confervoid thallus called "protonema," a reversion apparently to the primitive ancestral Alga. This elementary thallus, not being arrested by the appearance of sexual organs, is susceptible to subsequent differentiation; foliary buds are given off in places from its ramifications, the multiplication of cells at these points becomes regular, and little by little small laminæ assume the form of leaflets on a stem supported by radicles. These radicles are capable of producing new plants, and mosses propagate so energetically that extensive carpets may be formed without the aid of reproductive organs, and in some species fruiting plants are rarely met with. This great vegetative power seems entirely due to the absence or rarity of sexual function. The reproductive organs when present are however of the greatest morphological importance. These are distinguished as "antheridia," or male, and "archegone," or female. At maturity antherozoïds escape from the antheridia and impregnate the archegone. The "oospore" contained in the archegone produces a new cellular plant, which develops more or less within the archegone in which it is born, and finally becomes the organ called "fruit" in the Mosses. This so-called fruit is in reality a distinct plantlet, called a "sporogone," which by asexual generation or simple multiplication gives birth to the spores, and these spores, falling in damp places, again give rise to new thalli or moss plants. This alternate generation is unknown among Algæ. We have thus in the Mosses a new point of departure, the more important generation, being analogous to Algæ and tardily sexual, take on very complete morphological characters; the other generation, agamous, subordinate, and incapable of disengagement from the archegone in which it is formed, yet fundamentally an independent plant. The Hepaticæ are similar in growth, and both together present a stationary group which have elaborated a special kind of organic differentiation, but in a direction limited by biologic conditions. Derived from cellular thalli with "tardy sexuality," evolution has acted exclusively on the first generation; while the second, of newer origin and free from heredity, would have been susceptible of far more complete differentiation. The truth of this hypothesis becomes apparent when Ferns, Equisetaceæ, and Ophioglosseæ are studied.

The origin of these three groups is similar to that of the Mosses and Hepaticæ. Their spores give birth to a cellular thallus or "prothallus," which "precociously" produces numerous archegones and antheridia. The same process takes place as in the case of Mosses, except that the resulting "sporogone" is vigorous and speedily effaces the ephemeral life of the sexual plant. It promptly frees itself and takes root, its tissues become extremely diversified, and fibres and vessels, histological elements previously unknown, appear, and plants known as ferns, horsetails, &c., result. On the leaves of this highly-developed sporogone the sporangia are born which produce the spores, whose germination gives birth to the sexual prothallus. The precocious and abundant development of sexual organs almost immediately arrests the differentiation of the prothallus, and the primordial aërial Alga becomes completely subordinate. On the other hand the sporogone which succeeds became more and more developed and commenced a series which step by step has led finally to the most highly organised and most recent group of plants, the Angiosperms. The evolution which has given us those plants, which seem to an inattentive observer to form nearly the entire vegetation of the earth, is in the authors' opinion the result of a circumstance, doubtless almost insignificant in its commencement, and of which the first effects were to arrest by a precocious sexuality the organic differentiation of some of the primordial terrestrial plants. While everything seemed to unite to favour the evolution of those types with permanent thalli, and which produced Mosses and the Hepaticæ, other thalli of lower development found in the very causes which limited their differentiation, the starting point of a new vegetative system, that of the sporogone, the preponderance of which soon became manifest. In the Rhizocarps we see this species of development in a more advanced stage than in the Ferns. The sporogone has become more and more preponderating, and the prothallus scarcely disengages itself from the envelopes of the spore.

Ferns occasionally exhibit a tendency to a separation of the sexes, for the prothallus may be either male or female, but in the Rhizocarps dicœcity is more nearly realised, for the spores themselves are of two sexes—microspores and macrospores. The germination of the microspores consists simply in the production of tubes scarcely divided into cells, in one of which the antherozoïds are produced. In the macrospore, though a rudimentary prothallus is at first more or less apparent, this is quickly concealed by the extension of the sporogone developed within one of the archegones. With the disappearance of the rudimentary prothallus almost the last trace of the primordial cellular Alga disappears.

The prothallus is thus seen to be so reduced in the Rhizocarps that it seems almost as if the sporogone were disengaged directly from the macrospore. This sporogone follows otherwise the same histological development as in Ferns, but gives birth morphologically to a further departure. Certain fronds become differentiated into "sporocarps," a kind of fruit comprising both micro- and macrosporangia, and which in *Marsilia* attain remarkable complexity. This is the highest point of evolution seen in existing Cryptogams, for the Lycopods are rather a parallel development than an actual advance beyond the Rhizocarps. They are divided into Isospores, or true Lycopods, in which the sporogones bear but one kind of spore, producing monœcious prothalli only; and the Heterospores (Selaginellæ and Isoetes), in which the sporogone bears both microspores and macrospores.

In the microspores of heterosporous Lycopods a single cellule represents the male thallus, and appears a useless appendicle to the antherozoïd-producing cellules. The macrospore germinates into two cellular masses, corresponding to the female thallus, which, although never

entirely disengaged from the envelopes of the spore, still produces true archegones destined to receive the impregnation of the antherozoïds.

In these, as in all the Metaphytes of which we have been speaking, the spores become detached before germination. While this caducity always characterises the microspore, the macrospore separates less readily from the sporogone, and the method in which the sexes in primordial plants became separated is doubtless indicated by this tendency. The microspore always represents the male and the macrospore the female thallus, the physiological functions which they have to effect being very different. Activity characterises the male element, which always seeks the female element, necessarily more complex, voluminous, and charged with plastic substances. It is easy to conceive the possibility of the existence of a stage, a little above the existing heterosporous Lycopods, in which the microspores alone become detached before germination, and seek the macrospores while still attached to the fronds of the sporogone, which would then germinate on the plant and receive impregnation before their fall. It is true that we can say nothing definitely as yet respecting the extinct allies of the Lycopodiaceæ, which may have possessed this character, but the course of evolution requires this stage to have existed, and it is recognisable in the Gymnosperms and Angiosperms.

In these, the culminating development of the vegetable kingdom, the sporogone masks completely the primordial vegetative system, of which however there still remain traces. The sporogone, which has become differentiated into the most varied and complex plants with organs of the utmost delicacy and efficacy, invariably produces spores of two sorts. The microspores (or pollen grains) quit their sporangia (anthers) before germination, to fecundate the female spore, but impregnation no longer depends on the action of vibratile corpuscles, leaving an antheridium. The entire ancient life of the male prothallus with its cellular tissue and its antheridia is represented by a tube piercing the exospore or external membrane of the pollen grain and coming into contact with the female element. The male protoplasm is no longer in corpuscles, but in order to impregnate, directly traverses by endosmose the membrane of the pollinic tube. The gradations by which this reduction of the male prothallus has taken place are not preserved in any existing plant.

The manner in which the development of the female macrospore has been arrested is even more remarkable. A special macrosporangium or "ovule" is born in Phanerogams, on branches of the sporogone in which the leaves are transformed into what is called a flower, an organ not differing morphologically from the sporangium-bearing spikes of Cryptogams. That no complete interruption or hiatus really exists between these different types of vegetation is demonstrated by a study of the macrosporangia of Gymnosperms.

In these the macrospore or embryonic sac contained in the macrosporangium (ovule) germinates on the spot and gives birth to a true prothallus or primordial cellular vegetative system, which fills the entire ovule. On this inclosed prothallus of the Gymnosperms (Conifers and Cycads), called an "endosperm," archegones appear (the "corpuscules"), which are fecundated by the last rudiment of the male prothallus (the pollinic tube). This is accomplished while the macrosporangium is still attached to the sporogone, and results in the production of an embryo in place of the oospore of the archegone. This rudiment of the new sporogone is already well developed when the macrosporangium or seed becomes detached. The sporogone only apparently succeeds directly to another sporogone, for actually the primordial vegetative system has preserved its sexual function; concealed and reduced as it is, it has still presided over the earliest developments of the agamous phase of the plant.

In certain Gymnosperms (*Salisburia*), and as if to better demonstrate the successive stages which have led from the Cryptogams to Phanerogams, the pollinic tube has inaugurated its movement, and the seed, apparently ripened, falls from the tree before the formation of any corpuscles or archegones. These are scarcely developed in the ovule, before the penetration of the male organ operates fecundation and gives birth to the phenomena which result in the formation of the embryo.

In the Angiosperms these processes are further reduced and the macrosporangium still more concealed by the production of an ovary. In tracing the homology of the complex and delicate processes involved in the reproduction of Angiosperms the climax of plant-evolution is reached.

Enough has been said to show the scope and value of the work which Saporta and Marion have laboriously produced. That part which attempts to bridge the gap, hitherto perhaps the most complete break in the natural system, is of such great importance that I have almost quoted the authors' own words. The interpretations and ideas set forth may perhaps be insufficient to carry complete conviction, but it will be seen that the remainder of this work, which treats principally of palæontology, confirms the theories derived from study of existing plants.

PROF. ROBERTSON SMITH ON THE OLD TESTAMENT

The Old Testament in the Jewish Church. By Prof. W. Robertson Smith. (Edinburgh: A. and C. Black, 1881.)

THE only result of the "baiting" to which Prof. Robertson Smith has been subjected seems to have been the exact reverse of what his assailants intended. Forbidden to lecture upon Hebrew philology at Aberdeen, he has been invited to Edinburgh and Glasgow, there to detail to crowded audiences the method and conclusions of biblical criticism.

No one could be more fitted for the task he has undertaken than Prof. Robertson Smith. Clear-headed, acute, and learned, he had been a devoted student of natural science before he suddenly turned his attention to the Semitic languages and Old Testament criticism. The scientific habit of mind he had acquired was carried by him into his new studies, and it was inevitable that he should attach himself to that modern school of philologists and historians which by the application of the scientific method has revolutionised the study both of language and of history. He believed that the prin-

ciples of evidence and reasoning which held good of the language and history of Greece or Rome must hold equally good of the language and history of the ancient Jews.

The lectures he has now published under the heading of "The Old Testament in the Jewish Church," put in a popular and intelligible form the chief conclusions arrived at by modern critics in regard to the Pentateuch and its position in Jewish history, together with the evidence upon which they rest. The reader is led on from one point in the argument to another with admirable skill and clearness; nothing essential is omitted, while at the same time the whole chain of reasoning may be followed without difficulty by those who do not know a Hebrew letter and have never read a line of critical theology. Prof. Robertson Smith claims that there is no opposition between the results of critical inquiry and the fullest belief in the divine character of the Biblical record; on the contrary, these results, if frankly admitted, will be found to be confirmatory of the orthodox faith. Indeed the Professor's most relentless opponents ought to be gratified by the hard blows he deals at "rationalism," whatever that may mean.

With the theological aspect of the question we have of course nothing to do. But we must congratulate the Professor upon having found such large and sympathetic audiences to listen to an exposition of the mode in which the scientific principles of inductive inquiry have been applied to early history. The chief object of his contention is that the Levitical Law has taken its true place in the development of the Jewish nation; instead of coming at the beginning of the nation's existence, and so making the whole of its subsequent history unintelligible, it has been shown to have come at the end. Unknown to the most pious of the judges and kings, unknown equally to the prophets before the Exile, it naturally makes its appearance when Judah had ceased to be an independent state, when the free spontaneity of prophetic utterance was passing away, and when the priestly rulers of the returned exiles had no longer to fear the contamination of foreign idolatry or the erection of rival altars. The Levitical Law, according to Prof. Smith, follows the labours of the prophets; it does not precede them.

This result he claims to have obtained by questioning the Jewish records in accordance with the principles of scientific evidence. The credibility of a historical fact rests upon the authority of the documents or oral traditions that vouch for it, and naturally diminishes in proportion to the length of time between its supposed occurrence and the date of the earliest document in which it is described. The age and character, therefore, of a historical document must be closely tested and ascertained. The means for doing this are threefold: historical, literary, and philological. We must discover whether the historical conditions presupposed by the document agree with its assumed age, whether it bears marks of compilation and redaction, or has come to us straight from the hand of a single author, and whether the language in which it is written is as old as it professes to be. But when the age and character of the document have been thus determined, the scientific historian has still much to do. If its claims to antiquity can be substantiated we have still to ask whether the facts it narrates are the statements of a contemporary, or only the far-off echoes of a bygone tale. If, on the other hand, its claims are disallowed, we have yet to discover how much or how little of its assertions may be believed; what rests on first-hand evidence, and what is merely late tradition or the coloured narrative of the writer himself. And even when all this has been done, our work is not quite over. The facts we have extracted from our authorities must be pieced together and shown to follow in a natural and continuous stream of development. For in history as in nature the scientific method reveals to us the law of continuity and development, and whatever offends against this law cannot be admitted in a scientific reconstruction of the past. The school of historians to which Prof. Robertson Smith belongs believe they have proved that the traditional view of the Pentateuch and the Levitical legislation does offend against this law, and they would change and modify it accordingly. And in thus changing and modifying it they claim the support of history, of literature, and of philology.

OUR BOOK SHELF

Manuals of Elementary Science—Electricity. By Prof. Fleeming Jenkin, F.R.S. (London: Society for Promoting Christian Knowledge, 1881.)

THIS little work, of little more than a hundred pages, is a remarkable *tour de force*, since it contains in briefest language almost everything that can be taught, without using mathematical symbols, of the modern notions on electricity. It therefore well deserves to stand as a companion volume beside that remarkable primer of "Matter and Motion" of the late Prof. Clerk-Maxwell. The strong point of the present elementary work on electricity is the way in which it points out the connection between electrical (and magnetic) phenomena and the phenomena of other branches of physics as regulated by the law of the Conservation of Energy. So early as the sixth paragraph the fundamental idea of electric potential is introduced, a course which is surely to be commended, inasmuch as there is no more inherent difficulty in the mind of the beginner in conceiving of electricity as able to do work by moving from one position to another than of conceiving it as able to exert a force at a distance, while there can be no question that the former of these two conceptions is the more fruitful for expressing electric actions and reactions. The inherent connection between induction and charge is carefully insisted upon, and the beginner is told in simple language how the equal and opposite stresses between the two elements of an induction-pair, separated by an insulating medium, represent a store of energy whose seat is in reality in the intervening medium. Where so much pains has been taken to spare the beginner from having anything to unlearn, it is a pity that in the very first sentence our antiquated friends the "two imponderable fluids called positive and negative electricity" crop up. We also think it is a mistake to refer to a magneto-electric generator as a magneto-electric "engine" (as is done on page 107). The chapter on Electro-chemistry is admirable in every way. The following paragraph, on the perception of electricity, deserves to be quoted entire:—

"Our atmosphere is not only electrified, but presents such variety in the intensity and distribution of its electrification, that *a sense enabling us directly to perceive electricity* would frequently disclose a scene as varied as a gorgeous sunset. This sense would reveal the surface of solid bodies delineated by varying electrical density. Dielectrics would be transparent to the new sense, and conductors would be opaque, having their projecting edges, corners, and points marked with startling distinct-

ness. The effect of contact in producing or maintaining difference of potentials would be perceived by a difference in electric brilliancy, and this difference would vary with each re-arrangement of the objects. Every movement of our body, each touch of our hand, and the very friction of our clothes, would cause a play of effects analogous to those of light and shadow on the eye, while more highly electrified matter would bring into prominence by induction electrical differences between surrounding bodies. This speculation, however fanciful, helps us to conceive the omnipresence of electricity; and since the mechanical conditions required to excite sensation are fulfilled in the electrical relations between bodies at different potentials, there does not seem any very great boldness in suggesting that some living things may have *an electrostatic sense* so far developed as to be of use to them" (page 51).

Altogether this little work forms a very suitable introduction to its author's much more advanced and well-known "Textbook of Electricity and Magnetism."

The Natural History of the Cranes. A Monograph by the late Edward Blyth. Greatly enlarged and reprinted with numerous illustrations by W. B. Tegetmeier. (Published for the Author, 1881.)

THIS is an excellent monograph of an exceedingly interesting group of birds. On the arrival in 1873 of a pair of the beautiful white-naped cranes of Japan in London they were drawn by Mr. T. W. Wood for the *Field* newspaper, and the late Edward Blyth took the opportunity of publishing in the columns of that paper a monograph of all the then known species of crane. At the suggestion of Prof. A. Newton, Mr. Tegetmeier has republished these notes, inserting however much new matter that either want of space had prevented Blyth from incorporating, or that had come to hand since Blyth's death. Thus we have Wolley's graphic account of the nesting of the common crane in Lapland, Dr. Cullen's account of the nesting of the Demoiselle in Bulgaria, and even Col. Prjevalsky's account of a new species found at Koko-nor. Sixteen species, two belonging to the genus Balearica and fourteen to the genus Grus, are described. Mr. Wood's figures of *Grus leucauchen* are reproduced. There is a facsimile of the coloured figure of *Grus nigricollis* from Col. Prjevalsky's "Birds of Mongolia"; a spirited sketch by Prof. W. H. Flower of flocks of *Grus virgo* on the banks of the Nile; some copies of studies of cranes from Mr. Cutler's beautifully-illustrated work on Japanese ornament (charming studies); and a few woodcuts of anatomical details.

Cranes of one or more species are found everywhere, with the exception of South America, the Malayan and Papuan Archipelagos, and the scattered islands of the Pacific. The common European species, celebrated in all times for its migrations—

> "So steers the prudent crane
> Her annual voyage, borne on winds; the air
> Floats as they pass, fann'd with unnumber'd plumes"—

was at one time very numerous in the fenny districts of England; so possibly Milton knew the bird. The name is quite wrongly applied to the heron in Scotland and Ireland, while in America and Australia the white egret herons are also called cranes. Old Æsop's fable of the stork being captured in the evil companionship of the cranes, and being condemned to death for thus even associating with notorious plunderers of grain, indicates that he well enough knew the two kinds of birds; far better indeed, as Blyth truly remarks, than did that renowned master of mediæval painters, who commits the curious zoological mistake of introducing cranes instead of storks in his world-known cartoon of the Miraculous Draught of Fishes.

In common with many other gregarious birds, cranes always place sentinels as a lookout, while the rest of the flock will trustfully repose; and they likewise leave them on the watch while on their marauding expeditions to crops of grain.

Zoological Atlas (Including Comparative Anatomy) With practical directions and explanatory text for the use of students. 231 coloured figures and diagrams. By D. McAlpine. Vertebrata. (W. and A. K. Johnston, 1881).

THE object of this work is to help the student in the examination and dissection of the leading types of animal life. The author quotes Dr. Macalister's words, "That in a practical science such as zoology it is only by the examination of specimens that any knowledge of the science worth acquiring can be obtained, and the function of a book is to assist in practical study." Bearing this in mind, he has here tried to assist the student by giving descriptions and drawings of one selected specimen from each group of the vertebrates. The skate and cod have been chosen to represent the cartilaginous and bony fishes respectively; the salamander to represent the tailed amphibia; the tortoise to represent the reptiles; and the pigeon and rabbit to represent the birds and mammals. The various systems are well represented, with the exception of the muscular system, which perhaps has been wisely overlooked. There can be no doubt but that this Atlas will form an important addition to the working student's books. It should remove many elementary difficulties from his path.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Dr. Carnelley's Experiment with Mercuric Chloride

I WAS a little surprised to notice from a paragraph in Prof. McLeod's letter in NATURE, vol. xxiv. p. 28, that he had been unable to repeat Dr. Carnelley's experiment with mercuric chloride. Immediately after the publication of my former letter, it was remarked to me, that although I had shown hot ice to be an impossible commodity, perhaps Dr. Carnelley's assertion of the existence of solid mercuric chloride above its boiling point might still hold. I therefore repeated this experiment, and after overcoming a few preliminary difficulties, obtained a result similar to that with ice. The difficulties were these:—After solidifying a cylinder of mercuric chloride round the thermometer (to which it adhered at first), on heating, the mercuric chloride soon became detached and fell from the thermometer. It had therefore to be sustained in position round the thermometer, by a stout iron or copper wire. Another difficulty arose from the fact that the mercuric chloride soon became deeply pitted and fissured, so much so, that the thermometer was sometimes seen through holes a quarter of an inch deep. This pitting went on till the mercuric chloride cylinder, though not much reduced in diameter, became a mere network, the thermometer being visible in many places. The erosion seemed to take place more quickly next the bulb; making the holes in the cylinder widest at the interior. Another difficulty lay in the high temperature causing, as Prof. McLeod noticed, the rupture of the thermometer thread; but by using a very good thermometer, and keeping it as nearly vertical as was convenient, this was entirely obviated. A large condenser is not required, and I only used a piece of combustion tubing fully an inch in diameter and about twenty inches long, the thermometer with the cylinder of mercuric chloride being inserted at one end, and a tube connected with a Sprengel pump at the other. The results obtained are as follows:—Melting point of mercuric chloride, 271° (uncorr.); boiling point, 291° (uncorr.). The pressure was now reduced to 400 mm., and the tube heated until the temperature was constant, the pressure again reduced, another reading taken, and so on until a vacuum was reached, or the cylinder had become too porous to give correct readings.

By the use of Gimmingham's form of pump the exhaustion can be increased in a very short time, and the readings all obtained from one cylinder an inch in diameter. Three series of readings were taken agreeing very well with each other. At first there were discrepancies, owing to the porosity of the cylinder not being noticed, but these disappeared when care was taken. The temperatures were not corrected, as the results were not intended for publication, as I expected some other worker to repeat the experiment, but that not being the case I give the numbers as they are, premising that the temperatures, if corrected, would be 6° or 7° higher for the upper and 4° to 6° for the lower ones. The following are the numbers obtained :—

Pressure in millimetres.	Temperature of volatilisation.	Pressure in millimetres.	Temperature of volatilisation.
400	270	40	233
300	267	30	228
200	263	20	223
100	253	10	214
80	248	5	205
60	242	0	185

A determination done before those given above gave—

Pressure in millimetres.	Temperature of volatilisation.
68	245
10	222
5	210

But I do not place the same confidence on these numbers, as they were obtained in ignorance of the porosity of the solid; but they confirm the others. It appears from the above that mercuric chloride is no exception to the general law which makes the volatilising point rise or fall with the pressure. The low latent and specific heats of mercuric chloride make it not nearly so suitable an exponent of the truth of Regnault's conclusions as water; the latter allowing of a whole hour's continued experiment. I think after these experiments the idea of being able to raise solids in vacuo to temperatures above their ordinary volatilising or boiling points may be dismissed as inadmissible, except it may be in some rare case of allotropy. Private Laboratory, Sword Street, Glasgow

The Conservation of Electricity

BY the kind permission of Messrs. Macmillan and Co. I am allowed to quote the following paragraph from the preface to my "Elementary Lessons in Electricity and Magnetism," shortly to be published by them in their School Class Books Series, and now in the press. The preface is dated "March, 1881."

"The theory of Electricity adopted throughout is that Electricity, whatever its nature, is *one*, not *two*: that Electricity, whatever it may prove to be, is not *matter*, and is not *energy*: that it resembles both matter and energy in one respect, however, in that it can neither be created nor destroyed. The doctrine of the *Conservation of Matter*, established a century ago by Lavoisier, teaches us that we can neither destroy nor create matter, though we can alter its distribution and its forms and combinations in innumerable ways. The doctrine of the *Conservation of Energy*, which has been built up by Helmholtz, Thomson, Joule, and Mayer, during the last half century, teaches us that we can neither create nor destroy energy, though we may change it from one form to another, causing it to appear as the energy of moving bodies, as the energy of heat, or as the static energy of a body which has been lifted against gravity or some other attracting force into a position whence it can run down, and where it has the potentiality of doing work. So also the doctrine of the *Conservation of Electricity*, which is now growing into shape,[1] but here first enunciated under this name, teaches us that we can neither create nor destroy electricity, though we may alter its distribution—may make *more* to appear at one place and *less* at another—may change it from the condition of rest to that of motion, or may cause it to spin round in whirlpools or vortices which themselves can attract or repel other vortices. According to this view all our electrical machines and batteries are merely instruments for altering the distribution of electricity by moving some of it from one place to another, or for causing electricity, when heaped up in one place, to do work in returning to its former level distribution. Throughout these Lessons the attempt has been made to state the facts of the science in language consonant with this view, but rather to lead the young student to this as the result of his study than to insist upon it dogmatically at the outset."

[1] This is undoubtedly the outcome of the ideas of Maxwell and of Faraday as to the nature of electricity. It has nowhere been more excellently or pithily put into shape than in a discourse delivered by Dr. Oliver J. Lodge before the London Institution, "On the Relation between Light and Electricity," December 16, 1880 (NATURE, vol. xxiii. p 302).

The above paragraph is published at the present time because, since the date when my manuscript was sent to the publishers, a memoir has been presented to the Académie des Sciences bearing the title, "Sur le Principe de la Conservation de l'Électricité, ou seconde Principe de la Théorie des Phénomènes Électriques." Of this memoir, which is by M. G. Lippmann, only a brief extract has as yet been published in the *Comptes rendus* of the sitting of May 2, when it was read. In that short extract the general doctrine of the conservation of electricity is laid down with considerable clearness, and an elegant analytical expression of it is given in the briefest form, the author promising some examples of its application to the prediction of new and important phenomena. The publication of the complete memoir of M. Lippmann will no doubt be awaited with interest.

As my manuscript was placed in the hands of Messrs. Macmillan and Co. on the very day when the above extract was written, the phraseology used by M. Lippmann must have been adopted by him in entire independence of me. Since some weeks must elapse before my "Elementary Lessons" will be in the hands of the public, I wish to avoid, meantime, all chance of misunderstanding by taking the earliest opportunity, firstly, of making this acknowledgment, which is due to M. Lippmann, and secondly, of establishing my right to use the language of my preface as to the explicit enunciation of *the doctrine of the Conservation of Electricity*. SILVANUS P. THOMPSON

The Florence Herbarium

I BEG to forward to you the inclosed protest of the botanists of Florence against the proposed removal of the Herbarium and adjoining Botanical Garden at Florence to a new locality in that city.

It is well known to all botanists who have visited that city that, taking into account the importance of the herbarium, the admirable building in which this and the other collections are lodged, and the annexed botanical garden, the establishment at Florence deserves to rank amongst the first in the world, and is indeed scarcely second to any except that at Kew. It has an especial interest in the eyes of Englishmen, owing to the fact that it includes the invaluable collections of the late Mr. Barker Webb, which include, besides the type specimens of the Canary Island flora and of his other works, those still more important of Labillardière, of Ruiz and Pavon, and of Desfontaines, whose herbaria all passed into his hands.

Although well acquainted with the Florence Museum, and disposed to believe that it would be difficult to find another locality equally well adapted for the purpose, I was unwilling to express any opinion on the subject without full information as to the new arrangements proposed in substitution for those now so excellent.

Within the last month my friends Sir Joseph Hooker and Dr. Asa Gray have visited Florence, and have carefully examined the present building and its appurtenances, and also the sites to which it is proposed to remove the herbarium and botanic garden. I learn that they have expressed an unqualified opinion that the proposed new building is altogether unsuited for the purpose, and would too probably tend to the injury and ultimate loss of the herbarium, while the site of the proposed botanic garden is also an unfavourable one.

Sir Joseph Hooker has written a full statement of his views to Prof. Carnel, recently appointed Director of the Botanical Museum, who has not, I believe, as yet published his opinion on the subject.

Under these circumstances I venture to hope that you will publish the accompanying document, with a view to prevent the accomplishment of a design so injurious to natural science. Those who wish to associate their names with the protest are invited to send them to M. E. Sommier, Lung'Arno, Corsini, Florence. JOHN BALL

Florence, 5 *Mars*, 1881

A propos du déplacement projeté des collections botaniques du Musée d'Histoire Naturelle de Florence.

Lorsqu'au mois de Mai de l'année 1874 un grand nombre de botanistes de toutes les parties du monde se trouvèrent réunis à Florence, dans les salles des Collections botaniques fondées par feu le professeur Parlatore, M. le professeur Alphonse de Candolle fit observer "qu'une des choses les plus remarquables s'imposant à l'attention des membres du Congrès, était le Musée botanique, avec ses salles amples et commodes, où avaient lieu les séances du Congrès." ("Actes du Congrès Botanique international, tenu à Florence au mois de Mai 1874," pag. 220.)

Personne, alors, n'eût soupçonné que ce qui avait été jugé digne d'admiration par les hommes les plus compétents, serait déclaré mauvais et condamné à un bouleversement radical sept ans à peine après que ces paroles mémorables avaient été prononcées. Pour justifier l'abandon du Musée actuel, on prétexte l'inconvénient qu'il y a pour les étudiants fréquentant les cours de l'Institut des Études supérieures, place St. Marc, d'avoir à se rendre, pour une autre partie de ces cours, au Musée de Via Romana; et, afin de centraliser les édifices affectés aux études, on ne pense à rien moins qu'à opérer le déménagement des collections botaniques et à abandonner le jardin du Musée, avec toutes ses serres et annexes. En revanche, on parle de rendre à son ancien usage le modeste Jardin des Simples, situé à proximité du nouvel emplacement destiné aux herbiers. Mais a-t-on examiné si ce transport est réalisable, avantageux, et si le nouveau local de la place St. Marc, destiné à la Botanique, est adapté ou non à recevoir les herbiers et les autres collections?

Or ce local n'est autre que le bâtiment des anciennes écuries des Grands Ducs de Toscane, occupées plus tard par la cavalerie italienne. Pendant une série non interrompue de près de trois cents années, ces écuries ont logé des chevaux en très-grand nombre, et c'est là que l'on se propose de colloquer des collections de plantes, d'un prix inestimable, et si faciles à se détériorer sous l'influence de l'humidité! Il est vrai qu'en sacrifiant d'énormes sommes pour reconstruire l'édifice à peu près de fond en comble, on ferait peut-être disparaître les traces du long usage auquel il a servi; mais il est permis de se demander si, même dans ce cas, on obtiendrait jamais des salles comparables à celles du Musée actuel, soit en beauté, soit en salubrité, soit en solidité.

Ce projet étant scutenu et sur le point d'être mis à exécution par des personnes respectables, mais étrangères à la Science et par conséquent incompétentes, nous Soussignés, amis de la Botanique résidents à Florence, croyons de notre devoir, dans l'intérêt des collections, de protester contre ce déplacement, et, afin de donner plus de poids à notre protestation, nous invitons les Botanistes qui se sont trouvés à Florence lors du Congrès de 1874, ainsi que tous ceux qui connaissent les salles actuellement affectées aux collections de plantes, à joindre leurs voix à la nôtre pour empêcher qu'on ne mette à exécution un projet que nous croyons hautement préjudiciable à nos plus chères études.

Nous prions en conséquence les Botanistes italiens et étrangers de vouloir bien employer leur influence afin que le projet en question soit abandonné, et que les sommes, dès à-présent destinées à une œuvre inopportune et risquée, soient de préférence employées à augmenter le matériel scientifique du Musée actuel, par l'achat de collections de plantes vivantes et desséchées (surtout de plantes cryptogames) et d'ouvrages manquant à notre bibliothèque botanique et à acquérir les armoires et étagères, nécessaires pour placer et mettre en ordre une immense quantité de paquets d'herbier, actuellement sans emploi et inutiles aux études, ainsi qu'à adapter les serres du Jardin botanique aux exigences modernes, en commençant par y faire les réparations reconnues de première nécessité.

Barometer Pumps

Communications from Mr. Sprengel have been published, in which he has defended his claim to be the inventor of the mercury barometer-pump. As long as he confined himself to this claim I had no right to interfere, but by his letter in your previous number (vol. xxiv. p. 53) he claims to be the inventor or father of all kinds of barometer-pumps. His right to this claim I dispute; for in May, 1847, I obtained a patent for improvements in sugar-refining, one of which is the conversion of a vacuum-pan into a large barometer by placing under a common vacuum-pan a long pipe in a perpendicular position, which acts as a pump whereby the sugar is taken out of the pan by its own weight in the long pipe, and thereby the vacuum in the pan is not destroyed, and the process of sugar-boiling is carried on continuously. The syrup to be boiled is added in the pan above, while the boiled sugar is taken out below through the barometer-pump. The specification of my patent was published in patent journals in London in 1847, and it is possible that Mr. Sprengel took the idea of his mercury barometer-pump from my sugar barometer-pump. But at all events Mr. Sprengel was not the first inventor of a barometer-pump. I claim that honour.

The Hutton Collection of Fossil Plants

It has only within the last few days come to my knowledge (indeed only to-day authoritatively) that the Hutton Collection of Fossil Plants, at present deposited in the Museum of the Natural History Society of Northumberland and Durham, at Newcastle, had been named by the curator, Mr. Richard Howse, prior to the compiling by myself of a Catalogue of the Collection, published in 1878 by the North of England Institute of Mining and Mechanical Engineers. The labels on the specimens, referred to in the Catalogue, were therefore Mr. Howse's, and not, as I until now imagined, either William Hutton's original ones, or mere copies of them.

Moreover an unsigned MS. list of the specimens in the Collection, agreeing with the labels, with which I was furnished by the Mining Institute, and which was used freely by me in drawing up the Catalogue, must now be regarded as the result of much time and labour spent by Mr. Howse in identifying and naming the whole of the Hutton Collection.

I trust you will allow me space in your paper to acknowledge now what I should have made a point of acknowledging in the preface to the "Catalogue," had I been made acquainted with the facts of the case at the time. G. A. Lebour

College of Physical Science, Newcastle-upon-Tyne, May 18

"How to Prevent Drowning"

Mr. MacCormac's valuable article induces me to call attention to a prevalent error.

Almost every treatise on swimming tells the beginner that every one can float without exertion. Even Mr. MacCormac seems to imply that "lying quite still with the mouth shut and the head thrown well back in the water" is enough to insure any one against sinking. Now this may possibly be true for most men, but certainly not for all. I am a practised swimmer, fond of the water, and have often tried. Going through all the orthodox motions of the deep breath, the folded arms, and the head thrown back, I go down instantly. This is in fresh water; in salt I believe I can just float, but have seldom had a good opportunity of trying. The fact is that men are very different in buoyancy. I have seen a man float motionless with head and shoulders out of the water. Others may be even denser than I am. Most men believe themselves capable of coolness and presence of mind. They should remember that these will neither supersede the art of swimming nor alter the laws of gravity.

St. John's College, Cambridge E. Hill

The Effects of Pressure on the Germination and Growth of Plants

The following experiments may be of interest to vegetable physiologists:—On April 7, at 11 p.m., two sets of mustard-seeds—five in each set—were sown on pieces of moist cotton-wool, arranged as follows:—One piece was placed in a small bottle, which was then secured to the curved extremity of a glass tube, into the long arm of which mercury was poured till a height of forty-five inches was reached above the level of the metal in the shorter arm. The second piece, with its seeds, was placed in an exactly similar bottle, the neck of which was then made to dip beneath mercury, the bottle, of course, like the one soldered on to the tube, being inverted. This bottle was then placed beside the first.

The two sets of seeds were thus in exactly similar conditions, except for the increased atmospheric pressure and the compression of the atmosphere in the one case as compared with the other. The following was the course of development:—By 9 a.m. of the 9th three of the seeds under the 2½ atmospheres of pressure had protruded their radicles, and this protrusion by 12 p.m. of the same day had become considerable, while as yet there was no indication of commencing germination in any of the seeds of the second set. By 10 a.m. of the 10th these latter had just begun to germinate, the radicles of the seeds under high pressure being at the time a fourth and a third of an inch long.

Henceforward, however, the rapidity of development was reversed. The seeds, under ordinary pressure, grew rapidly, and their cotyledons became of a deep green colour; while the development of those under the high pressure became permanently arrested and the cotyledons of one that had entirely escaped from the seed-coats remained as etiolated as though they had been grown in absolute darkness.

They were allowed to remain untouched for eight days, when, as there was no change, the bottle was removed from the tube and simply allowed to stand inverted in the place it had formerly occupied. The two—out of the five—seeds which had hitherto remained unchanged now rapidly germinated, and grew into vigorous green young plants.

Does a greatly increased atmospheric pressure or a greatly compressed air prevent the development of chlorophyll, and while it stimulates germination does it prevent growth?

Liverpool, April 27 WILLIAM CARTER

[This is an interesting observation, and seems to suggest a new and comparatively unworked field of investigation—the effect of different amounts of atmospheric pressure on plant-life. With regard to the decomposition in the presence of chlorophyll and under the influence of sunlight, of carbon dioxide, it is remarked by Dehérain ("Cours de Chimie agricole," pp. 25, 26) that the conditions are analogous to those affecting the combustion of phosphorus. This is not luminous in pure oxygen at ordinary pressure, but becomes so immediately the oxygen is diluted with nitrogen or hydrogen, and still more when the pressure is much diminished. Boussingault has shown that leaves will not decompose pure CO_2 at the ordinary atmospheric pressure; but a small cherry-laurel leaf placed in the pure gas decomposed a cubic centimetre of it at a pressure of 17m. (*Compt. rend.*, 1865, t. lx. p. 872.)]

The Magnetic Survey of Missouri

IT may interest some of your readers to know that, although our State Legislature absolutely refused to do anything to aid in the Magnetic Survey of Missouri, refusing by a "crushing" vote even to authorise county officers to have a true meridian established, the work will still go on. A gentleman of St. Louis, whose name is withheld at his own request, has assumed the entire expense, and we shall now begin a more minute examination of the Missouri, Grand, and Osage valleys. We shall hereafter travel by wagon, and shall do the work where it is most needed in order to disclose the real directions of the isogonic lines. F. E. NIPHER

An Optical Illusion

THE illusion described by Mr. Wilson and commented on in an editorial note is anything but a novel one. An apparatus for the experiment was purchased by the Birmingham and Midland Institute, along with a quantity of optical apparatus, from Mr. Robert Addams, in, I think, 1857. Within the last few years I have noticed that the experiment is described and explained in Priestley's "Light and Vision." I am writing from home, or would give the exact reference. C. J. WOODWARD

Cambridge, May 23

I SHOULD like to know whether the following is a general experience, or only a peculiarity of my own vision?

If I stand with a source of light—a lamp or a window—at one side of my head, so that the light falls strongly on one eye only, and look, successively or simultaneously, at the images of a piece of white paper as seen by my two eyes, the image seen by the eye next the light is greenish white, and that seen by the eye farthest from it is light buff.

If instead of white paper I use the gilt edges of a book, the image seen by the eye next the light is of a beautiful golden green; the other is of a brassy yellow, almost orange.

This phenomenon does not appear to depend on any effect of dazzling, for the experiment succeeds perfectly with very moderate degrees of illumination. JOSEPH JOHN MURPHY

Old Forge, Dunmurry, co. Antrim, May 23

The Speaking Tube Anticipated?

HAS the following appeared anywhere in this connection as yet, or not? If not, please allow it to appear in NATURE with this qualification only, that the italics are mine.

Describing the "speaking trumpets or pipes which ran, we are told, along the whole length of the Wall," Bruce says ("The Roman Wall," by the Rev. John Collingwood Bruce, p 76), that Drayton long ago sang of them as follows in his "Polyolbion":—

> "Townes stood upon my length, where garrisons were laid
> Their limits to defend: and for my greater aid
> With turrets I was built, where sentinels plac'd
> To watch upon the Picts: to me my makers grac'd
> *With hollow pipes of brasse, along me still they went,*
> *By which they in one fort still to another sent*
> *By speaking in the same to tell them what to doe,*
> *And soe from sea to sea could I be whispered through.*"

ORIGIN OF THE ENGLISH MILE[1]

IT is known that the mile of 1609 metres long passed among English geographers and navigators as being the length of the terrestrial arc of 1′; in other words they made the degree equal to 60 of these miles. In reality it contains 69·5; there is thus an error of about one-sixth. This error, if it existed long among our neighbours, which I do not know, must have caused many a shipwreck. It has had another very remarkable result; it nipped in the bud the discovery of the law of universal attraction. The first time that Newton's great idea presented itself to his mind the proof failed him. because he made use of the common English mile to calculate the radius of the earth. He renounced the idea for a long time, and only took the calculation up again when he learned the results of Picard's measurement of a degree in France. Whence comes this defective estimate? Certainly it does not proceed from any effective measurement, for the worst degree measurements, among those which have been really made, and not fictitious measurements, like that of Posidonius, are far from presenting errors of such magnitude. English geographers then must have committed some mistake in taking their mile from ancient documents.

So long as navigation was limited to the waters of the Mediterranean, and to coasting along the western shores of Europe, it was scarcely necessary to trouble about the value of this element; but from the time that the discoveries of the Spaniards and Portuguese opened out a much vaster field, sailors were compelled to make some inquiry into the matter. I suppose that the English navigators applied to their geographers, and that these found nothing better to consult than Ptolemy, the great, the only authority in these matters. But Ptolemy himself refers to Eratosthenes; he says that he verified the measurements of the latter and found the same result, viz. 500 stadia for the terrestrial degree. I have thus been led to examine the measurement of Eratosthenes. According to the documents which historians have preserved, Eratosthenes measured the great arc of meridian which separates the parallels of Syené and Alexandria, and finally found 700 stadia to the degree. This is how he worked:—He observed at Alexandria, certainly by means of a gnomon, the zenith distance of the sun at

[1] Paper read at the Paris Academy of Sciences by M. Faye (*Comptes rendus*, xcii. No. 17).

midday in the summer equinox, and thus found 7° 12′. It is added that at Syené the bottom of the wells was fully lighted by the sun on that day, so that Eratosthenes concluded zero for the zenith distance of that body. I believe rather that the Greek astronomer caused an observation to be made at Syené with a gnomon, an instrument then very common in Egypt, and that that distance resulted from an effective observation, as well as in the case of Alexandria. We shall see that this conjecture is perfectly justified. We know that the observations made on the dark shadow of a gnomon bear a constant error equal to the semi-diameter of the sun, or, to speak more accurately, that they give the zenith distance of the upper edge of that body. The ancients do not seem to have remarked this; and in fact, as they deduced from their observations only the obliquity of the ecliptic or the epoch of the solstice, it did not concern them, for by combining the observations of the summer with that of the winter solstice, the error in question disappeared from the difference. But it is exactly the same here, since we have not to do with absolute latitude, but with the difference of latitude of two places at which the centre of the sun is found at midday on the same side of the vertical. Thus the amplitude 7° 12′ concluded by Eratosthenes is correct; it has moreover the advantage of not being sensiby affected by refraction.

Here is a first verification. On opening the *Connaissance des Temps* we find—

	°	′
For the latitude of Alexandria	31	12
,, ,, Syené	24	5
Difference	7	7

instead of 7° 12′. The difference, whatever may be the cause, is very small.

Here is a second and more delicate verification. The latitude of the point in Alexandria, where Eratosthenes observed, could not differ much from that which we have given. By adopting that and 7° 12′ for the zenith distance of the upper edge of the sun at the winter solstice we find 31° 12′ − (7° 12′ + 16′) = 23° 44′ for the obliquity of the ecliptic. Syené gives 24° 5′ − 16′ = 23° 49′. Is it possible that in the year 250 B.C. the obliquity of the ecliptic was from 23° 44′ to 23° 49′? From 1750 A.D. to 250 B.C. is 2000 years. At the rate of 48″ diminution per century the obliquity would be

$$23° 28′ 18″ + 48″ \times 20 = 23° 44′.$$

The observation of Eratosthenes at Alexandria is then authentic, and moreover very precise. That of Syené presents an error of only 5′.

There remains the geodetic operation. Egypt was the only country of antiquity which rejoiced in a survey. The valley of the Nile was very populous at that epoch, as far as Syené, and no doubt the survey extended thus far. Eratosthenes must have had every facility for procuring the necessary documents. He must have taken into account the difference of longitude of 2° 59′ which exists between the two cities, without having had to determine it directly. I regard, then, the distance of 5000 stadia, in round numbers, as being quite as accurate as the other parts of his operation, and as applying to the arc of meridian comprised between the parallels of the two cities.

We finally conclude from this 694·4 stadia for the degree. The Greek astronomer gave, in round numbers, 700 stadia. What was this stadium?

To reply to this question I calculate the arc of meridian from Alexandria to the parallel of Syené, with the actual element of the terrestrial ellipsoid. It is 797,760 metres. At the rate of 5000 stadia we find 159·55 metres for the stadium. At the rate of 600 feet for the stadium, the foot adopted by Eratosthenes would be 0·266 metres. This was then the ancient Egyptian foot, which we now reckon at 0·27 metre; and in fact it was with this foot that the survey of Egypt must have been made. By this reckoning the 5000 stadia give—

$$5000 \times 600 \times 0·27 = 810{,}000 \text{ metres},$$

showing a difference of 12,240 metres, partly owing to that of the points of departure, partly to the error which we perhaps make in the length of the Egyptian foot in carrying it to 0·27 metre. Thus the measurement made in Egypt, more than 2100 years ago, by an able Greek astronomer, is as good as authentic. All the existing causes of uncertainty do not alter it more than one-sixth. It is certainly not from this quarter that the error can come for which we seek.

Nor is it in the measurement of Ptolemy, for he tells us he went through the same operations and found the same results; only he gives 500 stadia to the degree instead of 700. This difference is evidently due to the fact that Ptolemy, who lived 400 years after Eratosthenes, under another domination, did not make use of the same foot. In fact he employed the stadium of 600 Phileterian feet, and as this foot is about 0·36 metre, while the ancient Egyptian foot was only 0·27 metre, he had to reduce the 700 stadia of his predecessor to $700 \times \frac{27}{36}$ = 525, or 500 in round numbers.

These estimates are confirmed, finally, by the Arabian astronomers, who measured, in 827 A.D., an arc of 1° in the plains of Mesopotamia. They found fifty-six miles, and concluded that they had thus verified the number of Ptolemy. The Arab mile being 2100 metres, the arc measured is found to be 117,600 metres, which corresponds to a stadium of 235 metres. This is very nearly the Phileterian stadium of 216 metres, except the error of the measurements seven times more possible on so small an axis, and the uncertainty of our existing estimate of the Arabian mile in the time of the Kalif Almamoun.

To resume: the estimate of Ptolemy is only a sort of conversion of the excellent measurement of Eratosthenes in units of another epoch and of different length. It would thus lose a little of its first precision; but, such as we find it in Ptolemy, the English geographers were fully justified in taking it for the basis of a valuation of the arc of 1′ and of offering it to the navigators of their country. Only, and it is here the mistake lies, they believed that the great Greek astronomer of Alexandria must have made use of the Greek foot. This is one and a half hundredths larger than the English foot. If the English geographers of the sixteenth century had strained this valuation ever so little, and had carried it to $\frac{1}{100}$ths, they would have found 630 English feet for the stadium, which they believed to be 600 Greek feet, and these 630 feet or 210 yards, multiplied by 500, would give them 105,000 yards for the degree, and exactly 1760 yards for the mile. The English mile, then, has evidently been deduced from the measure of Ptolemy; its error of one-sixth is solely due to the fact that the Greek foot has been confounded with the Phileterian foot.

LAURENTIAN GNEISS OF IRELAND

IN 1863 Dr. T. Sterry Hunt pointed out the resemblance of some specimens of rocks and minerals from Donegal which he had examined to those of the Laurentian series of North America. These rocks and minerals have been described by Dr. Haughton and Mr. R. H. Scott, who have pointed out that the "typical Donegal granite" is really a metamorphic bedded rock, containing in some places bands of crystalline limestone or marble. Outside the granite district are the newer series of schists, quartzites, and limestones, which occupy the whole of the Promontory of Innishowen, and were identified by the late Prof. Harkness with the Lower Silurian metamorphic series of the Highlands of Scotland. These two groups are shown on Griffith's Geological Map of Ireland, and it

will be seen on an inspection of this map that the quartzite series is represented as terminating obliquely against the margin of the granite or gneiss. This obliquity has never (as far as I can discover) been explained. The prevalent opinion seems to have been that the newer series has been converted into the older by increased metamorphic action. For some time past I never studied Griffith's map without the impression that the obliquity was due to unconformity of stratification, and on the determination of this point plainly rested the question whether the granitoid gneiss was, or was not, of Laurentian (or "Archæan") age.

Having had the advantage of a visit to some of the sections in the North Highlands of Scotland, in company with my colleague, Mr. R. G. Symes, under the able guidance of Prof. Geikie, last summer, I was in a position much more favourable for undertaking the investigation of this interesting question than would otherwise have been the case; and in the recent visit to Donegal I was accompanied by Mr. Symes and Mr. Wilkinson, of the Irish Survey, who rendered material aid in this preliminary survey.

The knowledge thus obtained has been of essential service, and I am happy to be able to state that we have succeeded in identifying the Donegal gneissic series, both as regards its mineral characters and its unconformable relations to the Lower Silurian series with the Laurentian beds of Sutherland and Ross. The relations of the two series in Donegal are similar to those which are to be observed in the Laxford and Rhiconich districts, where the Cambrian sandstones and conglomerates are absent, and where, in consequence, the Lower Silurian quartzites and limestones rest directly on the old gneiss These conditions can be clearly made out in the neighbourhood of Lough Salt, near Glen, where successive beds of quartzite, limestone, diorite, and schist of the Lower Silurian series terminate abruptly at the margin of the gneissic series. We satisfied ourselves that this truncation of the Silurian beds is not due to faulting, as there is no appearance of disturbance or fracturing amongst the strata on either side. Similar—though less clear—indications were observable all along the eastern or southern margin of the gneissose district. Nor was the unconformity confined to the Silurian series, as we found that the beds of this formation came into contact with these of different geological horizons amongst the gneissic series at different places; there occurs, in fact, a double unconformity.

When examining the gneissic series we were often struck by the resemblance presented by the beds to those of Sutherlandshire, particularly amongst the lower portions. The massive foliated rock formed of red orthoclase, greyish oligoclase, green and black mica, and quartz, traversed by pegmatite veins, is identical in character with that from Rhiconich and Laxford; while the upper beds are interstratified with hornblendic and micaceous schists like those near Scourie. The occurrence of thin beds of white and grey marble, with sphene, idocrase, &c., in the Laurentian gneiss, seems peculiar to the Irish rocks, and brings them into close relationship with those of Canada.

A new basis has thus been formed for the whole superstructure of the Irish geological formations as deeply seated as that of any other country, and there can be little doubt that as the Laurentian beds have thus been recognised on the clearest evidence in Donegal, they may be recognised also in parts of Sligo, Mayo, and Galway, where the evidence is not so clear.

As I hope to have an opportunity of more fully stating the case at the forthcoming meeting of the British Association at York, it will be unnecessary here to enter on further details. I will only add that in speaking of the gneissic series as "Laurentian" I only wish it to be understood that the beds are contemporaneous with those underlying the Cambrian and Lower Silurian series of the Scottish Highlands. Whether they are really the representatives in time of the Laurentian beds of Canada is immaterial for my present purpose. For my own part I consider the preponderance of the evidence to be in favour of the view that they are in the main representative.

EDWARD HULL

Geological Survey Office, Dublin

JOSEPH BARNARD DAVIS

AFTER a short illness Dr. J. Barnard Davis died last week at his residence at Hanley, Staffordshire, being about eighty years of age. In the summer of 1820, while still a student, he made a voyage to the Arctic regions in the capacity of surgeon to a whaling ship. In 1823 he became a licentiate of the Society of Apothecaries; twenty years later he passed the College of Surgeons, and in 1862 took the M.D. degree of the University of St. Andrew's. In 1868 he was elected into the Royal Society. Soon after obtaining his first qualification he settled down in the Potteries, and but for what he describes, in the preface to his "Thesaurus Craniorum," as "an accidental conversation with a friend," might have remained through life leading the useful but uneventful life of thousands of general practitioners in the country, unknown beyond his immediate sphere of work. That accidental conversation however lighted up some smouldering embers of an interest which long before had been kindled by the lectures of Lawrence on the Natural History of Man, and led to the researches which resulted in the publication (in conjunction with the late Dr. Thurnam) of the "Crania Britannica," or delineations and descriptions of the skulls of the aboriginal and early inhabitants of the British Islands, illustrated with sixty-seven beautifully-executed lithographic plates, completed in 1856. Besides this Dr. Davis published many memoirs on anthropological subjects, including one "On Synostotic Crania among Aboriginal Races of Man," one on "The Osteology of the Tasmanians," one on "The Peculiar Crania of the Inhabitants of Certain Groups of Islands in the Western Pacific," and one published in the *Philosophical Transactions* for 1868, "On the Weight of the Brain in different Races of Man."

But it was by his famous collection, rather than by his writings, that Dr. Barnard Davis was best known, and the time, labour, and money which he spent in gathering it together is his greatest service to science. During a long period of time, in which the national and other public collections were losing the golden opportunities afforded by the extension of English adventure and commerce to all parts of the world, and allowing races to die out or their characteristics to become obliterated by intermixture with others, Dr. Davis let no chance of procuring specimens pass by, and was unwearied in his correspondence with travellers, collectors, and residents in foreign lands. He thus amassed together within a few rooms of a small house in Staffordshire a collection of crania and skeletons, nearly all with carefully-recorded histories, far exceeding in size that in all the public museums of the country put together, and only surpassed in very recent years by any of the Continental collections. In 1867 he published a catalogue called "Thesaurus Craniorum," which not only contains a description and many figures of the specimens, with 25,000 measurements, but which is also a perfect storehouse of information, owing to the literary references with which it abounds. The publication of this catalogue made the collection so well known that it naturally led to its increase, and in 1875 it became necessary to publish a supplement on the same plan, in which the history of the literature of the subject was continued to date. The catalogue and supplement contain descriptions of more than 1700 specimens, mostly crania.

Warned by failing health and increasing years of the

desirability of making arrangements for the future preservation of the collection, Dr. Davis entered into negotiations about a year ago with the College of Surgeons of England, by which body it was purchased, and in whose museum it has now been arranged in such a manner as to be accessible to all workers at anthropology. Such a collection as this, well cared for in a public museum, is a solid and permanent increase to the wealth of the country, for even if the methods of investigation now used are superseded by others, and the present literature comes to be looked upon as obsolete, the specimens will remain as materials for building up the history of the human race; and as the interest in the subject increases—as it certainly will—many of these evidences of the physical structure of people passed or passing away will come to be objects of priceless value. W. H. F.

M. H. MILNE-EDWARDS

WE referred some time ago to the fact that a medal, subscribed for by a number of his admirers, had been presented to the venerable zoologist, M. H. Milne-Edwards. No one better deserves such a recognition,

Medal presented to M. H. Milne-Edwards.

and none know better than the French how to do such an honour gracefully and impressively. Our illustration is reproduced from *La Nature* of May 7, where will be found a pretty complete list—and it is a long one—of M. Milne-Edwards' works. The medal, a production of some artistic merit, is the work of M. Alphée Dubois.

THE ZOOLOGICAL RESULTS OF THE SOCOTRAN EXPEDITION

AT the meeting of the British Association in 1878, upon the motion of Mr. Sclater, a Committee, consisting of Dr. Hartlaub, Sir Joseph Hooker, Capt. J. W. Hunter, Prof. Flower, and the mover, was appointed to take steps for the investigation of the natural history of Socotra. Socotra, it was stated, was one of the few spots in the world which seemed never to have been trodden by the foot of the naturalist, and would in all probability be found to contain distinct insular forms, of which it would be highly interesting to know the relations, and to secure specimens for our collections.

The grant of 100*l.*, given by the Association for this excellent object, having been subsequently increased by two sums devoted to the same purpose out of the Government Fund of 4000*l.* administered by the Royal Society, the Committee felt strong enough to proceed to action, and in the winter of 1879 were fortunate enough to secure the services of Prof. J. B. Balfour, of the University of Glasgow, for a special expedition to the island.

Prof. Balfour left England on January 9, 1880, accompanied by Alexander Scott, a gardener from the Royal Botanic Gardens, Edinburgh, as collector, and reached Aden by the French mail on the 24th, where he obtained every sort of advice and assistance from the civil and naval authorities for his expedition. Owing to adverse winds and other difficulties Prof. Balfour did not manage finally to reach Socotra until February 11, when the party, which had been reinforced by the addition of Lieut. Cockburn of the 6th Royals and a corps of attendants from Aden, were put on shore at Gollonsir, a village situated at the north-west end of the island, by H.M.S. *Seagull*. In his report to the Socotran Committee Prof. Balfour gives the subjoined account of his subsequent proceedings:—

"Making in the first instance Gollonsir our headquarters, we explored the adjacent country to the south and south-west until February 25, when we struck tents, and sending our heavy baggage and stores by sea, started to march to Hadibu. We took four days to accomplish this, reaching Hadibu late on the night of the 28th inst.

"Having communicated to the Sultan the fact of our arrival, he came to Hadibu on March 1, when we had an interview.

"Establishing our *depôt* now on the Hadibu plain, about a mile from the town, we spent the time until the 7th inst. investigating the magnificent Haggier range of hills shutting in on the south the Hadibu plain.

"On March 8, leaving a tent-Lascar in charge of the *depôt* at Hadibu, we started upon a trip to the eastern end of the island, going eastward along the northern side and returning westward by the southern side of the island. During this trip we reached Ras Momé, the extreme eastern headland. Camp at Hadibu was again entered on March 18.

"As yet we had not seen much of the southern parts of the island, so on March 22 we left Hadibu on our last excursion. Crossing the Haggier range we emerged upon the southern shore at Nogad, traversed the coast-line for some distance, and then recrossed the island so as to

come down upon Kadhab village on the north side. We regained Hadibu on the 27th inst."

From Hadibu the party were conveyed back to Aden in H.M.S. *Dagmar*, and arrived at the latter port on April 9.

The two months thus spent in Socotra were certainly not sufficient for the proper investigation of its fauna and flora, though considering the time occupied very satisfactory results, as will be seen further on, were obtained. As observed by Prof. Balfour in his report, what has been done by the expedition is but a fragment of what remains to be accomplished. In exploring the island he deemed it better, considering the short time of the sojourn, rather to attempt to cover as much ground as possible, with the view of obtaining a representative collection, than to examine in detail a limited tract of country. By doing this much barren land was travelled over, and many rich and fertile spots were necessarily only superficially looked at. Especially amongst the hills of the Haggier range there are valleys which would well repay a careful and extended investigation. The expedition must, therefore, be considered only preliminary, for Prof. Balfour feels assured that a rich harvest awaits any collector who may hereafter visit the island.

"If, at any future time," Prof. Balfour observes, "an expedition is sent to the island, it would be well if the date of its arrival were timed so that it should have the last months of a year and the first months of the following upon the island. Our expedition reached the island too late in the year, so that before we left the heat was so intense as to prevent our doing so much work as we desired. Again, the inaccuracy of our knowledge of the geography of the island is a point to which the attention of future expeditions should be directed. The chart based on Wellsted's observations is the only available one, and that is so incomplete and incorrect as to be almost useless to any one moving about the island."

Collections in all branches of natural history were made by Prof. Balfour's expedition, Prof. Balfour, as might have been anticipated, devoting himself specially to the botany of the island. As arranged by the Socotran Committee, the first set of the zoological specimens have been sent to the British Museum, and that of the plants will go to Kew when Prof. Balfour's memoir on them has been published. The rocks and geological specimens have been placed in the hands of Prof. Bonney of Cambridge.

The collections are as yet but imperfectly worked out, but sufficient has been done to give results of very great interest in every branch of natural history.

The Birds, reported upon by Mr. Sclater and Dr. Hartlaub,[1] are found to belong to thirty-six species—generally "North-East African in character, being mostly such as are included in Heuglin's 'Ornithologie Nord-ost-Afrikas.'" Six however are peculiar to the island, the most remarkable of them being a new form of sparrow with a very thick bill, which is named by Messrs. Sclater and Hartlaub *Rhynchostruthus Socotranus* (Fig. 1). It is however possible that the *Rhynchostruthus* and other new species may still turn up on the peninsula of Gardafui, of which the zoology is almost unknown to us.

Mr. Butler's report on the Butterflies and Moths captured by Prof. Bayley Balfour and his assistants in Socotra[2] tells us that of the thirteen species of which examples were brought, not less than seven were new to science. "Of the new forms five are allied to previously-recorded types from the following localities :—one from the Comoro Islands, one from South-West Africa, one

Fig. 1.—*Rhynchostruthus Socotranus.*

Fig. 2.—*Tropidiphorus Balfouri.*

from Zanzibar, and two from Arabia. Without the help of these last two it would therefore have been impossible for any one not acquainted with it to guess at the locality from which this collection had been obtained."

The land-shells obtained in Socotra have been assigned to Lieut.-Col. H. H. Godwin-Austen, F.R.S., for examination, and his report on the Cyclostomaceæ was read before the Zoological Society on February 1 last.[1] Col. Godwin-Austen states that the Socotran Cyclostomaceæ, as a whole, "are, as might have been expected, African and Arabian in character, the relationship being certainly, as regards the operculated forms, more Arabian than African. The collection contains a number of very distinct, fine, and interesting forms, of which some were already known, but many are new, and considerably extend the list of Socotran species. The large area of limestone formation on the island is especially favourable to the existence of these creatures, while island conditions have as usual modified and increased the species."

"Judging from the land-molluscan fauna of Socotra," continues Col. Godwin-Austen, "there is strong evidence that the island was once directly connected with Madagascar to the south. We know the great antiquity of that island, and it is not unreasonable to suppose that in Socotra, the Seychelles, Madagascar, and Rodriguez, we have the remnants of a very ancient, more advanced coast-line on this western side of the Indian Ocean, which line of elevation was probably continuous through Arabia towards the north. With an equally advanced coast on the Indian side, the Arabian Sea would, under these con-

ditions, have formed either a great delta, or a narrow arm of the sea into which the waters of the Indus and Euphrates drained. Such conditions would have admitted of the extension of species from one side to the other, which the later and more extensive depression of the area, as shown in Scinde, afterwards more completely shut off."

Amongst the more remarkable of the operculated land-shells described by Col. Godwin-Austen is a new species of *Tropidiphorus*, which is proposed to be named *T. Balfouri* after its discoverer (Fig. 2).

The Reptiles collected by Prof. Balfour in Socotra have been worked out by Dr. Günther[1] and Mr. W. T. Blanford, Dr. Günther taking the Snakes and Amphisbænians, and Mr. Blanford[2] the remaining Lacertilians. Both of these collections were found to be of considerable interest. Among the snakes is a new form allied to *Tachymenis*, which Dr. Günther has proposed to call *Ditypophis*, and a new species of *Zamenis* (*Z. Socotræ*). Both these indicate an alliance with the circum-Mediterranean fauna. On the other hand the Socotran Sand-Asp (*Echis colorata*) belongs to an Arabian and Palestine species, while the Amphisbæna of Socotra (*Pachycalamus brevis*, gen. et sp. nov.) has its nearest allies in Eastern and Western Tropical Africa. Of the six species of lizards of which examples were in Mr. Blanford's series, three proved to be new to science.

At the same meeting of the Zoological Society Mr. Charles O. Waterhouse read a paper on the Coleopterous Insects which had been collected by Prof. Bayley Balfour in Socotra. The number of species of which examples were collected was stated to be twenty-four, and showed that the fauna of Socotra, judging from this collection, was distinctly African. Twelve of the species were described as new to science.

It will be seen, therefore, that although the zoological collections made by Prof. Balfour were very small in each group—in some cases almost of a fragmentary character—the results in every case present features of great interest. It is obvious that, judging from what is thus known, Socotra must possess—what was thought scarcely probable by many at the time the scheme for exploring it was first started—an indigenous fauna of considerable extent, one well worthy of further investigation, which the Socotran Committee, we believe, are quite resolved to undertake if they can obtain the necessary means. As regards the flora of Socotra we have said nothing, because Prof. Balfour, who has himself undertaken the investigation of the botanical collections, has not yet completed his task. But a preliminary examination has shown, we believe, that his series embraces about 150 absolutely new flowering plants, amongst which are from fifteen to twenty representatives of new genera—so that it is manifest that, like the fauna, the flora of Socotra possesses a strong autochthonous element.[3] Of this we hope to be able to give some account when Prof. Balfour is further advanced in his work. Meanwhile there can be no question that the Socotran Committee have accomplished a most useful bit of work, and that in this case, at all events, the public money devoted to scientific research has been well applied.

A GEOLOGIST'S NOTES ON THE ROYAL ACADEMY

ONLY of late years has the importance of accuracy in the drawing of rock structure been recognised either by artists or by the general public. For this we are indebted to no one so much as to Mr. Ruskin, whose chapters on the subject in the fourth volume of "Modern Painters" should be read again and again by every student who considers the faithful representation of Nature not unworthy of the aims of Art. It is true that some of the greatest among the older masters—as Titian or Dürer—rendered with great spirit and considerable accuracy the more salient features of rock structure, but from one cause or another they seldom entered into details, and were rather prone to exaggeration. The majority, till almost the present time, appeared to consider themselves unfettered, and "improved" upon Nature in accordance with the fancied requirements of the principal theme of their pictures. Some of the results may be seen in the volume to which we have referred. Within the last few years a due estimate of the special excellencies of Turner's work has produced a salutary influence, and more than one artist (like Elijah Walton, to speak only of the dead) has grappled successfully with the difficulties of rock structure. Thus the boulders, studied apparently from lumps of modeller's clay, the dilapidated crags, tottering like habitual inebriates, the attenuated peaks, which might have been decapitated with a walking-stick, are rapidly disappearing from the walls of our exhibitions. In many pictures however we still perceive more of good intention than of knowledge, and the number of those who cannot be said to "draw with the understanding" is by no means small.

We venture then to offer a few remarks on rocks as they are represented on the walls of the Royal Academy. In No. 13, "Gorse-cutting," passing clouds render the hillside in the background rather vague, but it may be doubted whether this is the only cause of an indefiniteness in the rock-structure, which is certainly also observable in that of the foreground. 28, "Llyn and Nant Gwynant," exhibits much careful mapping-out of the rocks, but cannot otherwise be said to be successful. There is a want of character in the craggy hillside in 55, "A Mountain Road," and the boulders are flat and indefinite, as though the artist had inserted them in his studio when the memory of their appearance in the field was beginning to fade from his mind. The same inability to seize the dominant characteristics of the rocks appears in 80, "Waiting for the Ferry." In 85, however, the "Land of Streams," its artist has been much more successful. Mr. C. E. Johnson has given us a painstaking study of a mass of hard stratified rock, which, as it dips away from the spectator, forms outcropping, curving ledges, over which the water dashes. In these, and in the craglets, both in foreground and middle distance, the principal facts of bedding and jointing are accurately rendered. Not so, however, in 89, "The Head of Teesdale," where we are led to conclude that the rocks are modelled from the same material as those in the scenes of theatres. The artist of 98, "A Storm in the Desert," has been more careful, but unless there is something exceptional in the locality it is difficult to conjecture what the rock may be. A mountain streaked with snow in the background of 122, "A Sermon in the Hayfield," is carefully studied, but still is rather wanting in character, and the colouring strikes us as crude. Mr. C. E. Johnson has again been successful in "The White Sands of Iona" (188), which is a very careful rock study. Rough craglets either of granite or of the granitoid gneiss, common on the western coast of Scotland, crop out among the slopes of sand. Of some the upper parts are smooth and polished, exhibiting traces either of the action of glaciers, like many another reef around the Western Highlands, or possibly in this case an example of the gentler attrition of blown sand; the rocky knolls in the middle distance should also be noticed. "The Scapegoat" (211) is a picture which causes us some little perplexity. There is an appearance of careful study both in the foreground craglets and in the bare mountains, which make up the scenery of this "Land not inhabited"; but still it is difficult to decide upon the

[2] "On the Lizards collected by Prof. Bayley Balfour in Socotra." (*Ibid.*)

[3] A very fine new *Begonia* from Socotra, of which tubers brought home by Dr. Balfour have flowered at Kew, is figured in the April number of the *Botanical Magazine*, tab. 6553.

actual character of the rock or the locality which the animal has reached. The great block in the foreground, upon which the scapegoat is standing, might be either a limestone or a felstone. The same rock constitutes the nearer mountain, and this, judging from the peculiar way in which the dominant joint planes alter their direction, can only be igneous. Hence we must assume it to be a felstone with a rather platy jointing. If this be the case, then the mountain-crests are exceptionally sharp, and the structure to which this is due is insufficiently indicated. The same general character is maintained in the distant mountains, but these are even more jagged. The picture suggests a combination of some Sinai photographs, rather imperfectly understood, with memories, which have become vague, of the Southern Alps. Might it not also be doubted whether such a waterfall as that on the right would occur in a "lone land" on the borders of Palestine? In the "Diamond Merchants" (258), if we do not wrongly identify the lighthouse on the distant skerries, the scene represented is in the immediate neighbourhood of the Land's End. The rock there should be granite, and the structure of the craglet in the foreground will accord with this, though the colour is unusual for that district; but the cliffs beyond much more resemble, especially in a sort of streakiness, some of the stratified rock locally called "killas." In "Past Work" (489), by the same artist, there is a similar uncertainty of treatment in the rocks, showing that he has not thought them worthy of that appreciative study which he has bestowed upon most matters connected with the sea. The locality of 271, "The First to look out for the Homeward Bound," may be presumed to be also Cornwall; but the rocks belong to quite a new type, and if they are anything, must be some kind of hard mudstone. 315, "Mountain Tops," is bold in colouring and in design, but can scarcely be regarded as successful. The floating clouds and the strong shadow into which the hills are cast by the gleaming sky, naturally obscure their structure, but would hardly account for the streakiness which they exhibit, as though the picture had been finished by wiping it down with a brush parallel to the leading outlines of each peak. It reminds us of an exaggeration of one of Turner's views of Loch Coruisk. 317, "A Babbling Brook in Ochmore," though hung rather too high, shows a careful study of gently-inclined strata. Mr. Brett, in "St. Ives' Bay" (340), gives us an excellent study of some granite rock in the middle distance of his picture; but this artist's mastery of his subject is brought out better in "Golden Prospects" (445). In the foreground is a ruined craglet or miniature "tor" of granite—a wonderfully truthful study; form, structure, texture of the rock, and the crisp crusting of dry lichens, perfectly rendered. The bald patches of granite amid the rough vegetation are admirably truthful, as is the hazy light, which renders the more distant cliffs, massive as they really are, almost ethereal. Out at sea, if we mistake not, is the Longships Lighthouse and its dangerous reef. Those who in any way equal Mr. Brett in his love for the Cornish coast will find it hard to tear themselves away from this picture of one of its grandest scenes. It may however be remarked that the general effect suggests a day early in the summer, but still the heather is in bloom.[1] There is some good promise in the limestone hills in 475, "A Grecian Tomb," though the hazy evening light is favourable to the avoidance of difficulties. In the "Ramparts of Idwal" (406), the colour is rather too monotonous, but a knoll with ledges of rock cropping out through rough turf and in the bed of a streamlet is admirably rendered. The peculiar texture of certain rocks composed of indurated volcanic ash seems to have impressed itself upon the artist. In "Hope Deferred" (419) there is little character in the rock; that however in the foreground may only be intended for very hard earth. In "Lofoden" (485) Mr. E. T. Compton gives us a careful study of a rather massive schistose rock in the mountain in the middle distance, and of one more granitoid in the foreground. The jointed structure of the latter and rather scaly aspect of parts of the former are well rendered, and the general effect of the picture is truthful, though the author has not selected for his subject one of the most characteristic parts of the Lofoden Islands. It would not be difficult to find a view like this in several spots on the mainland, but the wilder mountains of Hindö and Ost Vaagen are without a parallel in Scandinavia. Mr. C. Stuart's "Uncertain Weather" (507) is hung too high, but it appears to be a very careful study of the well-known crag overhanging the tarn in Cwm Buchan. In Mr. B. W. Leader's "Glyder Vawr" (521) we have a careful study of the felstone crags in the upper part of that mountain. The somewhat curving surfaces of outcropping rock in the middle distance of the picture and the boulders in the foreground are well rendered. The peculiar effect which the artist has chosen—a sudden gleam of sunlight glinting upon wet surfaces, gives to the rock an exaggeratedly rugged structure. The effect may be truthful, but is certainly rare, and we may doubt whether it is wise to select one producing results so abnormal. A rock in the foreground of "O'er the Heather" (539) is spotty, muddy, and indefinite. An unfamiliar effect has been chosen in "Kynance Cori as it appeared one day last January" (564), for a thick coating of snow rests upon the rocks. It is hung rather high, but the author does not seem to us to have quite succeeded in catching the peculiar structure and weathering of serpentine. "Nature's Decay" (905) also suffers from being too high. The pile of *débris*—earth and trunks and fallen branches—masks a good deal of the rock, but what is visible seems to be carefully drawn; that in a more distant ravine appears a little conventional. Sir R. Collier, in his "Glacier of the Rhone" (984), gives us one of his usual careful studies of rock and ice. The outcropping ledges and scattered boulders among the rough herbage are carefully drawn, making a most truthful rendering of a portion of rugged mountain-side. It may however be doubted whether the ice in the lower part of a glacier could be so generally blue as it is here represented. "Boulders at Rest" (1352) has some good points about it. The granite crag is carefully studied, and the structure is well rendered, but the two "natural" arches have a rather artificial aspect, and certainly weaken the effect of the composition. The boulders beneath have their individuality remarkably well preserved, but the artist has not been so successful in rendering their texture, which is rather woolly. In "The Dead Sea from Engedi" (1360) the artist appears to have striven honestly but not very successfully to record the scene. The rocks exhibit a streakiness of dubious authenticity, and convey to one the impression that while the general effect was felt by him the reasons for it were not understood.

Several other pictures we have been obliged to leave unnoticed, either because the rocks are obviously quite a subordinate part (though from our point of view that is no reason why they should not be accurate), or because the picture has been hung so high that it cannot be properly studied, and criticism might be unjust to the artists. The water-colour drawings we have not yet examined.

T. G. BONNEY

[1] While we were studying this picture a bystander described it to his companion as "No doubt the Needles idealised"

NOTES

THE death is announced of Mr. John Blackwall, F.L.S., at Llanrwst, on May 11, at the great age of ninety-two. He was elected a Fellow of the Linnean Society as far back as 1827, and was nearly its oldest member. His principal work was a magnificent illustrated Monograph of the British Spiders, published by the Ray Society about twenty years ago. He also

published a considerable number of papers on general zoology, in which the possession of keen powers of observation is everywhere evident. In 1834 a volume from his pen appeared under the title of "Researches in Zoology," a record of observations in the field, with deductions therefrom; a second edition was published in 1873.

THE *Launceston Examiner*, of March 14, announces the death of Mr. Ronald Campbell Gunn, F.R.S., at the age of seventy-three years. Mr. Gunn, who was born at the Cape of Good Hope, and landed in Tasmania in 1830, held successively several highly important official positions in the colony. Mr. Gunn's tastes, the *Examiner* states, were eminently scientific, but botany was his favourite study, and this subject he was indefatigable in pursuing. At an early period he was elected a Fellow of the Linnean Society of London, and subsequently a Fellow of the Royal Society of London, the highest scientific honour which can be conferred on any person. Mr. Gunn began to investigate the botany and natural history of Tasmania in 1831, and in the prosecution of his researches rambled over most of the colony. His botanical labours are recorded in Sir Joseph D. Hooker's "Flora of Tasmania," and accounts of his excursions and other scientific labours appear in the *Annals of Natural History*, *Journal of Botany*, &c. He was also editor of the *Tasmanian Journal*, a scientific serial published by the Royal Society of Tasmania. The late Mr. John Gould, in his valuable work upon the "Birds of Australia," acknowledges the assistance which he received while in Tasmania from Mr. Gunn. We may also mention that Mr. Gunn drew up for West's "History of Tasmania" a compendium of the zoology of Tasmania.

MR. ALBERT BRUCE JOY'S statue for the Harvey Tercentenary Memorial is now cast in bronze, and will probably be soon sent to Folkestone, the native place of the discoverer of the circulation of the blood, where a suitable site has been provided for it on that well-known promenade, the Lees. In modelling his successful statue Mr. Bruce Joy has closely followed the portrait of Harvey by Janssens, preserved in the Royal College of Physicians. Mr. Joy has also produced a reduction of the bust of Harvey.

THE Scottish Meteorological Society have received the observations made during last winter by Mr. A. O. Thorlacius, their observer at Stykkisholm, Iceland, from which it is seen that last winter was one of the severest of which there is any record, ice having formed in the harbour at least four feet thick. The only winter that can compare with the last during the present century was that of 1807, when the inhabitants of Grimso, an island lying nearly sixteen English miles off the coast of Iceland, walked across the ice to the trading station of Ofjord, a thing which was not known ever to have occurred before.

DURING his last visit to the United States, it will be remembered, Prof. Tyndall initiated a trust fund with the object of assisting students in physics who should show aptitude for original study and should wish to complete their education in Germany. It is stated that the fund has so far prospered as to furnish a moderate income for two students, who have just been nominated.

THE Glasgow Mechanics Institution, which as such has existed since 1823, has recently had its constitution altered and its name changed to that of "College of Science and Arts." At the close of the session Sir William Thomson, in distributing the prizes, mentioned that he had imbibed his first ideas of chemistry in the Mechanics Institution, and expressed himself much pleased with its present appearance, and the prospects of the Institution under its new name, and the superintendence of Mr. A. Jamieson, the principal. On this occasion the hall was lighted with Swan's electric lamps under arrangements very efficiently made by Mr. Jamieson.

THE Russian ladies seem to be advancing rapidly and surely in the direction of higher education. Besides the medical courses at St. Petersburg, there was opened two years ago in the same city a kind of ladies' university, being a series of courses for higher training in the mathematical, physical, and historical sciences. We learn now, from the annual report recently published, that notwithstanding all opposition on the part of Government to this institution, it has acquired further development. The third class is opened this year, and the fourth will be opened next year. The number of lady students, which was 789 in 1879, has already reached 840, and Prof. Famintzin observes that this number would have been much larger were it not for the obstructive regulations which are intended to check the further development of the institution. It is worthy of notice that the money necessary for the institution is collected from private sources—students' fees (5*l.* per annum) or by voluntary subscriptions. Like courses are already opened at Moscow and at Kieff, but the instruction given at Moscow is more superficial in what concerns natural science.

THE French Association for the Advancement of Science is to meet at Rochelle next year.

THE arrangements for the International Exhibition on the occasion of the International Medical Congress have within the last few days been nearly completed. The Exhibition itself, quite apart from the Congress, will be held in the eastern, the western, and the quadrant arcades of the Horticultural Gardens, and in some of the galleries of the Albert Hall. The Exhibition will be open from July 16 to August 13, but it is not yet decided whether there shall be any formal opening. That the Exhibition will be really international is indicated by the fact that there will be contributors from France, Germany, Austria, Italy, Belgium, Holland, Norway, and the United States. Much still remains to be done, but there is every prospect of the Exhibition being a credit to England. The secretary is Mr. Mark Judge, of the Parkes Museum of Hygiene, University College, Gower Street. From him particulars may be obtained.

IN the *Proceedings* of the Natural History Society of Glasgow Mr. J. A. Harvie Brown continues his reports on Scottish Ornithology. In the second part of the fourth volume we have the result of his observations, extending from October 1, 1879, to September 30, 1880. The utility of Mr. Harvie Brown's observation consists in a comparison of the occurrence of migratory birds in Scotland with the meteoric conditions of the season, and it seems perfectly certain that the increase or decrease in the number of our summer visitants depends greatly upon the strength and duration of favourable or adverse winds prevailing at the time they visit our shores. We are pleased to hear Mr. Cordeaux is also compiling records of birds noticed in the Humber district, and it would be interesting to naturalists if similar observations could be regularly made in different parts of Great Britain.

AN exhibition of microscopes and other scientific apparatus was held in January in place of one of the ordinary weekly entertainments at the Albert Institute, Windsor. This was so successful that another was held in April, and the Windsor and Eton Scientific Society formally constituted. The general meetings will take place monthly.

WITH respect to Burnham Beeches, we are told on good authority that the Corporation of London (who recently purchased the estate) have forbidden the picking of flowers on account of its disturbing the game! Among other things this prevents the science-masters at Eton going there on a half holiday with their

botanical boys or the members of the School Natural History Society.

In consequence of Mr. Bidwell's severe indisposition, he has been unable to prepare his paper on "Telegraphic Photography," announced to be read before the Applied Chemistry and Physic Section of the Society of Arts to-day, and the reading has, therefore, been unavoidably postponed.

Two strong shocks of earthquake occurred at Chio on the night of May 20, bringing down several of the houses that remained standing after the late catastrophe.

About a year ago the Boston Society of Natural History celebrated its semi-centennial by a jubilee meeting, and decided to commemorate the event by publishing a memorial volume consisting of memoirs from those among its present associates, eminent in various departments, whose circumstances enabled them to contribute. The New York *Nation* now announces the publication of the volume, a magnificent 4to of 600 pages, with 50 plates.

At a meeting of the Sanitary Institute of Great Britain, held on May 18, Dr. B. W. Richardson, F.R.S., in the chair, the discussion was continued upon the address given by the chairman, entitled "Suggestions for the Management of Cases of Small-Pox and Infectious Diseases in the Metropolis and Large Towns." Mr. Pearson Hill gave a number of facts relating to the Hampstead Small-Pox Hospital, and a letter was read from Dr. Tripe giving statistics relating to the hospital at Hackney. Dr. W. H. Corfield, Dr. Willoughby, Mr. Hempson Denham, and Mr. Bridgwater also took part in the discussion.

A trapper who recently arrived with musk-rat skins at Kingston, Ontario, delared, according to the *Colonies*, that the animal is becoming rapidly extinct.

The telephone is being introduced by the New Zealand Government into places where the telegraph does not exist. Between Collingwood and Motucka, a distance of fifty miles, a line has been opened, and is said to work admirably.

The work of the International Electrical Exhibition Commission is progressing, spaces having been allotted to the several countries on the ground-floor of the central transept. Meanwhile the general arrangement of the first floor has been decided upon. A saloon has been reserved for the Brush light and machines, and another for the Sawyer incandescent light. Mr. Edison will have a special saloon for his inventions. M. Maisme's incandescent light will be employed in lighting a saloon. The Jamin, Jablockhoff, Werdermann, and some others will each have its saloon. One of these is to be lighted by Tommassi voltaic elements.

It is announced from Nanaimo that further important discoveries of coal have been made in Vancouver Island.

It is believed in New Zealand that petroleum exists in large quantities in the North Island, and two companies are now engaged in sinking for it.

The additions to the Zoological Society's Gardens during the past week include an African Cheetah (*Felis jubata*), a Secretary Vulture (*Serpentarius reptilivorus*) from Africa, presented by Mr. James S. Jameson; a Plantain Squirrel (*Sciurus plantani*) from Java, a Chipping Squirrel (*Tamias striatus*) from North America, presented by Mr. W. Bassano; a Ceylonese Hawk-Eagle (*Spizaetus ceylonensis*) from Ceylon, presented by Mr. G. Lyon Bennett; a Loggerhead Turtle (*Thalassochelys caouana*) from the Atlantic Ocean, presented by the Earl Brownlow; three Bull Frogs (*Rana mugiens*), a Noisy Frog (*Rana clamata*) from Nova Scotia, presented by Mr. Hugo Müller; two Green Lizards (*Lacerta viridis*), European, received in exchange; a Crested Guinea Fowl (*Numida cristata*), a Long-nosed Crocodile (*Crocodilus cataphractus*) from West Africa, on approval; six Speckled Terrapins (*Clemmys guttata*), two Painted Terrapins (*Clemmys picta*) from North America, purchased; an Eland (*Oreas canna*), an Axis Deer (*Cervus axis*), born in the Gardens; three Spotted-billed Ducks (*Anas pœcilorhyncha*), bred in the Gardens.

GEOGRAPHICAL NOTES

The anniversary meeting of the Geographical Society was held on Monday last, Lord Aberdare, the President, occupying the chair. Mr. Markham read the report of the Council for the past year, which showed that, though the number of Fellows had not materially increased, the Society was in a satisfactory and prosperous condition, its assets being valued at close upon 40,000*l.*, exclusive of the map collection and library. After a reference to publications it was stated that an observatory which had been built and fitted up at the Society's house had been in constant use by students and others who wished to practise observing or to get their instruments adjusted. The large map of Eastern Equatorial Africa by Mr. Ravenstein was said to be approaching completion, but the rate of progress is seemingly slow, as only three out of twenty-four sheets are reported to be printed off. Catalogues of the library and map-collection are in various stages of preparation. The presentation of medals afterwards took place, when Capt. de Fonseca Vaz, naval attaché of the Portuguese Legation, received the Founder's for Major Serpa Pinto, acknowledging the honour in a very happy speech, in which allusion was made to his own geographical work on the Zambesi. Mr. C. R. Markham received the Patron's medal on behalf of Mr. Leigh Smith, who is at Peterhead, preparing for another voyage to Franz-Josef Land. The Schools' prize medals were afterwards distributed among the boys from the City of London School and Dulwich and London International Colleges, whose names we gave in a recent issue. Mr. Francis Galton announced some changes in future examinations, adding that Australia has been chosen as the special subject for 1881–2. The ballot having been taken for the new Council, Lord Aberdare was re-elected President, and Mr. R. H. Major was elected a Vice-President in the place of the Hydrographer of the Admiralty, and Mr. D. W. Freshfield and Lord Reay respectively Secretary and Foreign Secretary in the places of Mr. Major and Lord Arthur Russell. Among the new members of Council are Col. Grant, Gen. Pitt-Rivers, and Col. Yule. Lord Aberdare lastly read a short address, in which he gave an interesting retrospect of the geographical work of the past year. The usual dinner was held in the evening, when the principal speakers, besides Lord Aberdare, were Count Münster, Lord Houghton, and the American Minister.

The French, like the Italians, intend to explore the depths of the Mediterranean this summer; the Minister of Marine has decided to place the *Travailleur* at the disposal of a commission charged with the work of deep-sea exploration. The vessel will set out for the Mediterranean about the end of June.

The following explorations will be made during this summer by the Russian Mineralogical Society:—In the province of Kostroma, for the completion of a geologicacal map of the province, by M. Nikitin; the exploration of the Tertiary and Chalk formations in the province of Bessarabia, by Prof. Sintzoff; in the Polish province of Lublin, in continuation of the researches of the late Prof. Barbot-de-Marny; the examination of the relations between the old and the new Caspian formations in the province of Astrakhan, in the Bistchi and Djaksy-Sassyk Mountains.

The *Zritschrift* of the Berlin Geographical Society, No. 92, contains the conclusion of Herr Niederlein's paper "On the Scientific Results of an Argentine Expedition to the Rio Negro"; "Travels and Topographical Surveys in the North Chinese Province of Chi-li," by Dr. v. Mollendorff, with two maps; an interesting extract from a Hawaiian manuscript, by Dr. Ad. Bastian, and varieties from Australia, by Herr H. Greffrath. In the *Verhandlungen* of the same Society are papers: "On the Maories of New Zealand," by Dr. Beheim-Schwarzbach; "On Ice caves and Abnormal Ice-formations," by Prof. Schwalbe; and "On the South Carpathians," by Dr. Paul Lehmann.

At a recent meeting of the Bengal Asiatic Society, Mr. F. A. de Roepstorff read some interesting notes on the in-

habitants of the Nicobar Islands, a subject to which he has paid much attention. As the result of his visit and investigations last year he concludes that there is an element of Papuan origin among the people of the interior, and that this is strongly mixed with another not curly-haired race. It is true, then, as has been suggested, that there is a curly-haired race in the interior of Great Nicobar, but whether the Andaman Negrito and this tribe are related is very doubtful. Mr. Roepstorff hopes that future researches may enable him to settle the matter.

It is asserted in Algiers that a letter from Itarem, Chief of the Hoggar Tuaregs, has been intercepted, taking credit to himself for the massacre of Col. Flatters' expedition. This is the man who sent two of his relatives to Col. Flatters as a sign of goodwill, with which that officer professed himself so well satisfied.

The *Times* correspondent states that it is announced by Dr. Nachtigal that the first diet of German geographers will be held at Berlin on June 7 and 8.

ON DISCONTINUOUS PHOSPHORESCENT SPECTRA IN HIGH VACUA[1]

IN a paper which I had the honour of presenting to the Royal Society in March, 1879,[2] I drew attention to the fact that many substances when in high vacua and submitted to the molecular discharge by means of an induction coil, emitted phosphorescent light; and I especially mentioned the phosphorescent sulphides, the diamond, the ruby, and various other forms of alumina, crystalline and amorphous.

Pure alumina chemically prepared has very strong phosphorescence. Sulphate of alumina is dissolved in water, and to it is added an excess of solution of ammonia. The precipitated hydrate of alumina is filtered, washed, ignited, and tested in the molecular stream. It phosphoresces of the same crimson colour, and gives the same spectrum as the ruby.

Alumina in the form of ruby glows with a full rich red colour, and when examined in the spectroscope the emitted light is seen to be discontinuous. There is a faint continuous spectrum ending in the red somewhere near the line B; then a black space, and next an intensely brilliant and sharp red line, to which nearly the whole of the intensity of the coloured glow is due. The wave-length of this red line, which appears characteristic of this form of alumina is, as near as I can measure, λ 689·5 m.m.m. This line coincides with the one described by E. Becquerel as being the most brilliant of the lines in the spectrum of the light of alumina in its various forms, when glowing in the phosphoroscope.

This coincidence is of considerable interest, as it shows a relation between the action of molecular impact and of sunlight in producing luminosity. The phosphorescence induced in a crystal of ruby by the molecular discharge is not superficial, but the light comes from the interior of the crystal, and is profoundly modified according as its direction of vibration corresponds or makes an angle with the axis of the crystal, being quenched in certain directions by a Nicol prism.

Sunlight falling on the ruby crystal produces the same optical phenomena. The light is internally emitted, and on analysis by a prism is seen to consist essentially of the one brilliant crimson line, λ 689·5. This fact may account for the extraordinary brilliancy of the ruby, which makes it so highly prized as a gem. The sun not merely renders the red-coloured stone visible, as it would a piece of coral, but it excites the crystal to phosphorescence, and causes it to glow with a luminous internal light, the energy of which is not diffused over a broad portion of the spectrum, but is chiefly concentrated into one wave-length.

The crimson glow of alumina remains visible some time after the current ceases to pass. When the residual glow has ceased, it can be revived by heating slightly with a spirit-lamp.

After long experimenting with chemically pure alumina precipitated from the sulphate as above described, a curious phenomenon takes place. When sealed up in the vacuum two years ago it was snow white; but after being frequently submitted to the molecular discharge for the purpose of exhibiting its brilliant phosphorescence, it gradually assumes a pink tinge, and on examination in sunlight a trace of the alumina line can be detected. The repeated molecular excitation is slowly causing the amorphous powder to assume a crystalline form.

Under some circumstances alumina glows with a green colour. Ammonia in large excess was added to a dilute solution of alum. The strong ammoniacal solution filtered from the precipitated alumina was now boiled. The alumina which the excess of ammonia had dissolved was thereby precipitated. This was filtered off, ignited, and tested in the molecular discharge. It gave no red light whatever, but phosphoresced of a pale green, and on examination with a prism the light showed no lines, but only a concentration of light in the green.

Two earthen crucibles were tightly packed, the one with sulphate of alumina, the other with acetate of alumina. They were then exposed, side by side, to the most intense heat of a wind furnace—a heat little short of the melting-point of platinum.[1] The resulting aluminas were then tested in the molecular stream.

The alumina from the sulphate gave the crimson glow and spectrum line.

The alumina from the acetate gave no red glow or line, but a pale green phosphorescence.

In my examination of rubies, many pounds of which have passed through my apparatus, I have been fortunate enough to meet with one solitary crystal, not to the eye different from others, which emits a *green* light when tested in the molecular stream. All others act as I may call normally. The spectrum of this green-glowing crystal shows, however, a trace of the red line, and on keeping the discharge acting on it for a few minutes the green phosphorescence grows fainter and a red tinge is developed, the spectrum line in the red becoming more distinct.

Besides the ruby, other native forms of crystallised alumina phosphoresce. Thus corundum glows with a pink colour. The sapphire appears to be made up of the red-glow and the green-glow alumina. Some fine crystals of sapphire shine with alternate bands of red and green, arranged in layers perpendicular to the axis. Unfortunately it is impossible to prepare a tube for exhibition containing this variety of sapphire, as it is constantly evolving gas from the numerous fissures and cavities which abound in this mineral.

The red glow of alumina is chiefly characteristic of this earth in a free state. Few of its compounds, except Spinel (aluminate of magnesium), either natural or artificial, show it in any marked degree. All the artificially crystallised aluminas give a strong red glow and spectrum line. An artificially crystallised aluminium and barium fluoride phosphoresces with a blue colour, but shows the red alumina line in the spectrum. Spinel glows red, and gives the red line almost as strong as the ruby.

The mineral Spodumene (an aluminium and lithium silicate) phosphoresces very brilliantly with a rich golden yellow colour, but shows no spectrum line, only a strong concentration of light in the orange and yellow. A phosphorescing crystal of Spodumene has all the internal light cut off with a Nicol prism, when the long axes of the Nicol and the crystal are parallel.

It became of interest to see if the other earths would show phosphorescent properties similar to those of alumina, and especially if any of them would give a discontinuous spectrum; considerable interest attaching to a solid body whose molecules vibrate in a few directions only, giving rise to spectrum lines or bands on a dark background.

Glucina, prepared with great care, is found to phosphoresce with a bright blue colour, but no lines can be detected in the spectrum, only a concentration of light in the blue.

The rare mineral phenakite (aluminate of glucinum), sometimes used as a gem, phosphoresces blue like pure glucina, no trace of the alumina line being found in its spectrum. This mineral shows a residual glow after the current is turned off.

Thorina has very little, if any phosphorescence. This earth is however remarkable for its very strong attraction for the residual gas in the vacuum tube. On putting thorina in a tube furnished with well-insulated poles whose ends are about a millimetre apart in the centre, and heating strongly during exhaustion, the earth on cooling absorbs the residual gas with such avidity that the tube becomes non-conducting, the spark preferring to pass several inches in air rather than strike across the space of a millimetre separating the two poles. It is probable that this strong attraction for gas is connected with the great density of the earth thorina (sp. gr. = 9·4).

Zirconia gives a very brilliant phosphorescence, approaching

[1] Paper read before the Royal Society, May 19, by William Crookes, F.R.S.

[2] *Phil. Trans.* Part 2, 1879, p. 660.

[1] This operation was kindly performed for me by Messrs. Johnson and Matthey.

in intensity that of sulphide of calcium. The colour is pale bluish green, becoming whiter as the intensity of the discharge increases: no lines are seen in its spectrum.

Lanthana precipitated as hydrate and ignited shows no phosphorescence. After it has been heated for some time before the blowpipe it phosphoresces of a rich brown.

Didymia, from the ignition of the hydrate, has scarcely any phosphorescence; what little there is appears to give a continuous spectrum with a broad black band in the yellow-green. On examining the light reflected from this earth when illuminated by day or artificial light, the same black band is seen, and with a narrow slit and sunlight the band is resolved into a series of fine lines, occupying the position of the broadest group of absorption lines in the transmission spectrum of didymium salts.

Yttria shows a dull greenish light, giving a continuous spectrum.

Erbia phosphoresces with a yellowish colour, and gives a continuous spectrum, with the two sharp black bands so characteristic of this earth cutting through the green at λ 520 and 523. These lines are easily seen in the light reflected from erbia when illuminated by daylight. It is well known that solid erbia heated in a flame glows with a green light, and gives a spectrum which chiefly consists of two bright green lines in the same place as the dark lines seen by reflected light.

A curious phenomenon is presented by erbia when the spark passes over it at a high exhaustion. The particles of earth which have accidentally covered the poles are shot off with great velocity, forming brightly luminous lines, and, striking on the sides of the tube, rebound, remaining red hot for an appreciable time after they have lost their velocity. They form a very good visible illustration of radiant matter.

Titanic acid phosphoresces dark brown, with gold spots in places.

Stannic acid gives no phosphorescence.

Chromic, ferric, and ceric oxides do not appreciably phosphoresce.

Magnesia phosphoresces with a pink opalescent colour, and shows no spectrum lines.

Baryta (anhydrous) scarcely phosphoresces at all. Hydrated baryta, on the contrary, shines with a bright orange-yellow light, but shows no discontinuity of spectrum; only a concentration in the yellow-orange.

Strontia (hydrated) phosphoresces with a beautiful deep blue colour, and when examined in the spectroscope the emitted light shows a greatly increased intensity at the blue and violet end, without any lines or bands.

Lime phosphoresces of a bright orange-yellow colour, changing to opal blue in patches where the molecular discharge raises the temperature. In the focus of a concave pole the lime becomes red- and white-hot, giving out much light. This earth commences to phosphoresce more than 5 millims. below the vacuum, and continues to grow brighter as long as the electricity is able to pass through the tube. On stopping the discharge there is a decided residual glow. No lines are seen in the spectrum of the light.

Calcium carbonate (calcite) shows a strong phosphorescence, which begins to appear at a comparatively low exhaustion (5 m.m.). The interior of the crystal shines of a bright straw colour, and the ordinary and extraordinary rays are luminous with oppositely polarised light. Calcite shows the residual glow longer than any substance I have as yet experimented with. After the current has been turned off, the crystals shine in the dark with a yellow light for more than a minute.

Calcium phosphate generally gives an orange-yellow phosphorescence and a continuous spectrum. Sometimes, however, a yellow-green band is seen superposed on the spectrum.

Potash phosphoresces faintly of a blue colour. The spectrum shows a concentration at the blue end, but the light is too faint to enable lines, if any, to be detected.

Soda phosphoresces faintly yellow, and gives the yellow line in the spectrum.

Lithium carbonate gives a faint red phosphorescence. Examined in the spectroscope, the red, orange, and blue lithium lines are seen.

I have already said that the diamond phosphoresces with great brilliancy. In this respect perfectly clear and colourless stones "of the first water" are not the most striking, and they generally glow of a blue colour. Diamonds which in sunlight have a slight fluorescence, disappearing when yellow glass is interposed, generally phosphoresce stronger than others, and the emitted light is of a pale yellowish green colour.

Most diamonds which emit a very strong yellowish light in the molecular discharge give a continuous spectrum, having bright lines across it in the green and blue. A faint green line is seen at about λ 537; at λ 513 a bright greenish blue line is seen, and a bright blue line at λ 503, a darkish space separating the last two lines.

Diamonds which phosphoresce red generally show the yellow sodium line superposed on a continuous spectrum.

There is great difference in the degree of exhaustion at which various substances begin to phosphoresce. Some refuse to glow until the exhaustion is so great that the vacuum is nearly non-conducting, whilst others commence to become luminous when the gauge is 5 or 10 millimetres below the barometric level. The majority of bodies, however, do not phosphoresce till they are well within the negative dark space.

During the analysis of some minerals containing the rarer earths experimented on, certain anomalies have been met with, which seem to indicate the possible presence of other unknown elements awaiting detection. On several occasions an earthy precipitate has come down where, chemically speaking, no such body was expected; or, by fractional precipitation and solution from a supposed simple earth something has separated which in its chemical characters was not quite identical with the larger portion; or, the chemical characteristics of an earth have agreed fairly well with those assigned to it in books, but it deviated in some physical peculiarity. It has been my practice to submit all these anomalous bodies to molecular bombardment, and I have had the satisfaction of discovering a class of earthy bodies which, whilst they phosphoresce strongly, also give spectra of remarkable beauty.

The spectrum seen most frequently is given by a pale yellowish coloured earth. It consists of a red, orange, citron, and green band, nearly equidistant, the citron being broader than the others and very bright. Then comes a faint blue, and lastly two very strong blue violet bands. These bands, when seen at their best, are on a perfectly black background; but the parent earth gives a continuous spectrum, and it is only occasionally, and as it were by accident, that I have so entirely separated it from the anomalous earth as to see the bands in their full purity. Another earthy body gives a spectrum similar to that just described, but wanting the red, and having a double orange and double citron band. A third gives a similar spectrum, but with a yellow line interposed between the double orange and the double citron, and having two narrow green lines.

At present I do not wish to say more than that I have strong indications that one, or perhaps several, new elements are here giving signs of their existence. The quantities I have to work upon are very small, and when each step in the chemical operation has to be checked by an appeal to the vacuum-tube and to the induction-coil the progress is tediously slow. In the thallium research it only occupied a few minutes to take a portion of a precipitate on a platinum loop, introduce it into a spirit-flame, and look in the spectroscope for the green line. In that way the chemical behaviour of the new element with reagents could be ascertained with rapidity, and a scheme could be promptly devised for its separation from accompanying impurities. Here however the case is different: to perform a spectrum test, the body under examination must be put in a tube and exhausted to a very high point before the spectroscope can be brought to bear on it. Instead of two minutes, half a day is occupied in each operation, and the tentative gropings in the dark, unavoidable in such researches, must be extended over a long period of time.

The chemist must also be on his guard against certain pitfalls which catch the unwary. I allude to the profound modification which the presence of fluorine, phosphorus, boron, &c., causes in the chemical reactions of many elements, and to the interfering action of a large quantity of one body on the chemical properties of another which may be present in small quantities.

The fact of giving a discontinuous phosphorescent spectrum is in itself quite insufficient to establish the existence of a new body. At present it can only be employed as a useful test to supplement chemical research. When, however, I find that the same spectrum-forming earthy body can always be obtained by submitting the mineral to a certain chemical treatment; when the chemical actions which have separated this anomalous earth are such that only a limited number of elements can possibly be present; when I find it impossible to produce a substance giving

a similar discontinuous spectrum by mixing together any or all of the bodies which alone could survive the aforesaid chemical treatment;—when all these facts are taken into consideration, and when due weight is given to the very characteristic spectrum reaction, I cannot help concluding that the most probable explanation is that these anomalies are caused by the presence of an unknown body whose chemical reactions are not sufficiently marked to have enabled chemists to differentiate it from associated elements.

THE DISTANCES OF THE STARS[1]

EVERY one who is acquainted with the rudiments of astronomy knows that the sun with its attendant planets is merely an island group in the vast realms of space.

An island the size of this room in the middle of the Atlantic would hardly be more remotely apart from the surrounding shores than is our solar system from the bodies which surround it in space. To determine the distance from this solar system to the stars which surround it is the problem for our consideration to-night.

Recent Researches on 61 *Cygni.*—It is now almost exactly forty years (February 12, 1841) since the gold medal of the Royal Astronomical Society was awarded to Bessel for his discovery of the annual parallax of 61 Cygni. On that occasion Sir John Herschel delivered an address, in which he glanced at the labours of Struve and of Henderson as well as those of Bessel. The discovery of the distances of the stars was alluded to as "the greatest and most glorious triumph which practical astronomy has ever witnessed." From this date the history of our accurate knowledge of the subject may be said to commence. Each succeeding race of astronomers takes occasion to investigate the parallax of 61 Cygni anew, with the view of confirming or of correcting the results arrived at by Bessel.

[The parallactic ellipse which the stars appear to describe, having been briefly explained, the method of deducing the distances of the stars was pointed out.]

The attention of Bessel was directed to 61 Cygni by its proper motion of five seconds per annum. When Bessel undertook his labours in 1838 the pair of stars forming the double were in the position indicated on Fig. 1. When O. Struve attacked the problem in 1853 the pair of stars forming 61 Cygni had moved considerably. Finally, when the star was observed at Dunsink in 1878, it had made another advance in the same direction as before. In forty years this object had moved over an arc of the heavens upwards of three minutes in length.

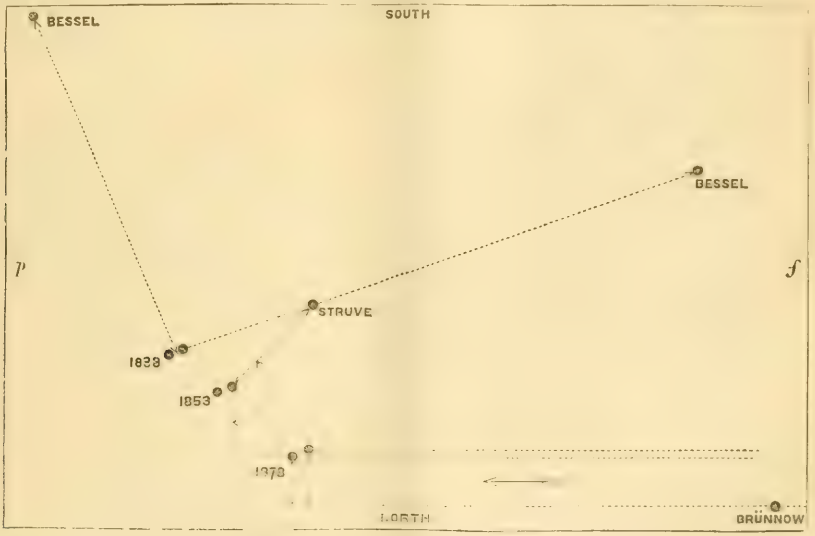

FIG. 1.—61 Cygni and parallax comparison stars.

The diagram contains four other stars besides the three positions of 61 Cygni. These are but small telescopic objects, they do not participate in the large proper motion of 61 Cygni, and they are undoubtedly much more remote from us. Bessel chose as the comparison stars the two objects marked with his name. He measured the distance from the central point of 61 Cygni to each of the two comparison stars. From a series of such measures he discovered the parallactic ellipse of 61 Cygni. He was led to the same ellipse by each of the two comparison stars.

Fifteen years later (1853) Struve undertook a new determination. He chose a comparison star different from either of those Bessel had used. Struve's method of observing was also quite different from Bessel's. Struve made a series of measures of the distance and position of the comparison star from 61 (B) Cygni. Struve also succeeded in measuring the parallactic ellipse.

There was, however, an important difference between their results. The distance, according to Bessel, was half as much again as Struve found. Bessel said the distance was sixty billions of miles; Struve said it could not be more than forty billions.

The discrepancy may be due to the comparison stars. If Bessel's comparison stars were only about three times as far as 61 Cygni, while Struve's star was about eight or ten times as far, the difference between Struve's results and Bessel's would be accounted for.

To settle the question, observations were subsequently made by Auwers and others; the latest of these investigations is one which has recently been completed at Dunsink Observatory.

Dr. Brünnow proposed and indeed commenced a series of measures of the difference in declination between 61 Cygni and a fourth comparison star. These observations were made with the south equatorial at Dunsink. The carrying out of this work devolved on the lecturer, as Dr. Brünnow's successor. Two series of observations have been made, one with each of the components of 61 Cygni. The results agree very nearly with those of Struve.

[1] Lecture at the Royal Institution of Great Britain, on Friday, February 11, by Prof. Robert S. Ball, LL.D., F.R.S., Astronomer Royal of Ireland.

On a review of the whole question there seems no doubt that the annual parallax of 61 Cygni is nearer to the half second found by Struve, than to the third of a second found by Bessel.

To exhibit the nature of the evidence which is available for the solution of such a problem, a diagram showing the second series of observations has been prepared (Fig. 2). The abscissæ are the dates of the second series of observations made at Dunsink. The ordinates indicate the observed effect of parallax on the difference of declinations between 61 (B) Cygni and the comparison star. Each dot represents the result of the observations made on the corresponding night. The curve indicates where the observations should have been with a parallax of 0″·47, the effect of the parallax in declination being only 0″·40. The discordances are not so great as might perhaps be at first thought. The distance from the top of the curve to the horizontal line represents an angle of four-tenths of a second. This is about the apparent diameter of a pennypiece at the distance of ten miles. The discordance between the observations and the curve is in no case much more than half so great. It therefore appears that the greatest error we have made in these observations amounts to but two or three tenths of a second. This is equivalent to the error of pointing the telescope to the top edge of a penny-piece instead of to the bottom edge when the penny-piece was fifteen or twenty miles off.

The entire quantity to be measured is so small that the errors, minute as they are, bear a large proportion to the parallax. In this lies the weakness of such work. By sufficiently increasing the number of the observations, and by discussing them with the aid of the method of least squares, considerable confidence may be attached to the results.

Groombridge 1830.—This star has been the subject of much parallax work. It has a telescopic proper motion of seven seconds annually. Mr. Huggins or Mr. Christie could perhaps ascertain by the spectroscope what its motion may be in the line of sight. From the theory of probabilities the total proper motion may not improbably be nine seconds. We shall however take it at seven seconds. The parallax has been determined by Struve and by Brünnow. It is very small, being one-tenth of a second. The actual velocity of 1830 Groombridge must therefore be at least 70 radii of the earth's orbit per annum, or 200 miles per second.

Newcomb has employed this result to throw light on the question as to whether all our stars form one system. If an isolated body in our system is to remain there for ever, the theory of gravitation imposes the imperative condition that the velocity of the body must not exceed a certain amount. Assuming that the stars are 100,000,000 in number, and that each star is five times as large as the sun, assuming also that they are spread out in a layer of such dimensions that a ray of light takes 30,000 years to pass it, Newcomb shows that the critical velocity is twenty-five miles per second.

As this is only the eighth part of the velocity of Groombridge 1830, we are thus led to the dilemma that either the masses of the bodies in our system must be much greater than we have supposed, or Groombridge 1830 is a runaway star, which can never be controlled and brought back.

Search for Stars with Parallax.—The lecturer has been engaged for some years at Dunsink Observatory in a systematic search for stars which have an appreciable parallax. Up to the present about three hundred stars have been examined. In the majority of cases each of these stars has been observed only twice. The dates of the observations have been chosen so as to render the effects of parallax as manifest as possible. It is not of course expected that a small parallax of a few tenths of a second could be detected by this means. The errors of the observations would mask any parallax of this kind. It seems however certain that no parallax could have escaped detection if it equalled that of α Centauri, *i.e.* one second of arc.

The stars examined have been chosen on various grounds. It had been supposed that some of the red stars were possibly among the sun's neighbours, and consequently many of the principal red stars were included in our list. No conspicuous parallax has however been detected in any of the red stars up to the present. Many of the principal double stars are also included in the list. Other stars have been added on very various grounds; among them may be mentioned the Nova, which some time ago burst out in the constellation Cygnus, and dwindled down again to a minute point. The earth's orbit however does not appear any larger when seen from Nova Cygni than from any of the other stars on our list.

Groombridge 1618.—We have however found one star which seems to have some claim to attention as one of the sun's neighbours. The star in question is Groombridge 1618. It lies in the constellation Leo, and is 6·8 magnitude. Groombridge 1618 has a proper motion of 1″·4 annually. From a series of measurements of its distance made on fifty-five nights from a suitable comparison star the parallax of Groombridge 1618 appeared to be about one-third of a second. As this seemed to be a result of considerable interest, measures were renewed for a second series of forty nights. The result of the second series confirms the first. Measurements of the position angle were also made at the same time. Some difficulties not yet fully explained have arisen, but on the whole the measurements of the position angle seem to confirm the supposition that the parallax of Groombridge 1618 is about one-third of a

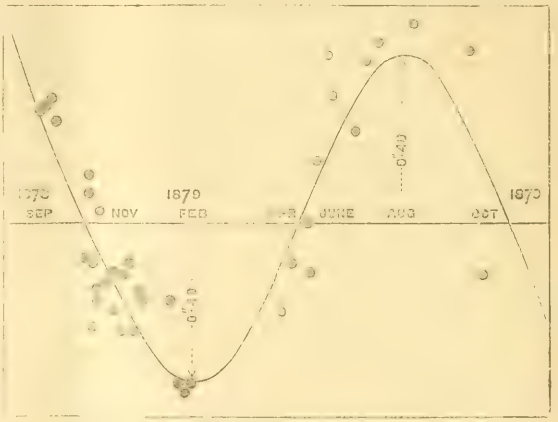

FIG. 2.—Parallax in declination of 61 (B) Cygni. Abscissæ indicate dates; ordinates indicate parallax; dots indicate observations.

second. The orbit of the earth viewed from Groombridge 1618 is about the same size as a pennypiece at the distance of seven miles.

Secular Proper Motions.—Geologists have made us acquainted with the enormous intervals of time which have elapsed since the earth first became the abode of living animals. Regarding a period of 50,000,000 of years as comparable with geologic time, some considerations were adduced as to the effect of proper motions during such an interval. It was pointed out that in all probability none of the stars now visible to the unaided eye can have then been visible from the earth.

The Nature of Space.—The possible connection of parallax work with the problems of the nature of space was then alluded to. It was shown that if space be hyperbolic the observed parallax is smaller than the true parallax, while the converse must be the case if space be elliptic. The largest triangle accessible to our measurements has for base a diameter of the earth's orbit, and for vertex a star. If the *defect* of the sum of the three angles of such a triangle from two right angles be in any case a measurable quantity, it would seem that it can only be elicited by observations of the same kind as those which are made use of in parallax investigations.

THE SECULAR INEQUALITIES IN TERRESTRIAL CLIMATES DEPENDING ON THE PERIHELION LONGITUDE AND ECCENTRICITY OF THE EARTH'S ORBIT

A PAPER on this subject, by the Rev. Dr. Haughton of Trinity College, Dublin, was read before the Royal Society on February 24 last. Dr. Haughton shows that the two inequalities in question depend upon terrestrial radiation only, and in no way upon sun-heat.

Having noticed that the hottest and coldest time of day *follows* noon and midnight by an interval often considerable; and in like manner that the hottest and coldest days in the year *follow* midsummer and midwinter[1] by an interval often of many days; Dr. Haughton saw in these facts a close analogy with the diurnal tides, which follow the sun or moon's meridian passage by an interval of some hours.

Dr. Haughton was thus led to solve the differential equation on which the problem depends, by assuming an expression similar to those so well known and so long employed in the mathematical discussion of the tides of the ocean.

The result fully justified the assumption of expressions similar to diurnal tidal expressions, for when the differential equation is integrated for a day and summed for a year, all the periodic terms disappear, and nothing is left but terms depending on the perihelion longitude and eccentricity, which represent the exact mathematical expression of the two inequalities first noticed by Adhémar and Croll.

The final result takes the form—

Mean annual temperature

$$= k\{(\Theta_0 + a) \pm (\alpha_1 \cos \varpi + \beta_1 \sin \varpi)e\} \quad . \quad . \quad (1)$$

where

k, = Constant,
Θ_0, = Mean annual temperature of place,
a, = "Control"[2] temperature of atmosphere at place.

α_1 and β_1 are defined by the following equations:—

$2\sqrt{\alpha_1^2 + \beta_1^2}$ = Range of annual temperature.

$\frac{\beta_1}{\alpha_1}$ = Tangent of the arc which represents the retardation of the maximum and minimum temperature.

ϖ = Longitude of earth's perihelion.
e = Eccentricity of earth's orbit.

Using Ferrel's temperature tables, Dr. Haughton finds the following maximum secular ranges of mean annual temperature:—

Maximum Secular Range

Latitude.	Northern hemisphere.	Southern hemisphere.
°	°	°
0	0·185 F.	0·185 F.
10	0·375 ,, ...	0·585 ,,
20	1·100 ,, ...	0·875 ,,
30	2·065 ,, ...	1·110 ,,
40	2·750 ,, ...	0·985 ,,
50	3·685 ,, ...	0·710 ,,
60	4·610 ,, ...	0·540 ,,
70	4·985 ,, ...	—
80	4·925 ,, ...	—

This table shows that the average maximum effect of the astronomical causes involved in perihelion longitude and eccentricity never can exceed 5° F. in the northern hemisphere, and barely exceeds 1° F. in the southern. At particular localities, where there is a great range of annual temperature, the effect may be somewhat greater. For example, at North Grinnel Land the range becomes 6°·5 F. It will be seen how little benefit this would confer upon that locality, when it is remembered that the present mean annual temperature of North Grinnell Land is 2°·42 F. *below* zero, and that by the secular range it could be raised to 0°·21 F. *above* zero, or depressed to 6°·29 *below* zero.

At Discovery Harbour Tertiary plant beds were found by the Arctic explorers, which indicate a *July temperature greater than 63°·7 F.*; the present July temperature of Discovery Harbour is 37°·2 F. above zero, or *only five degrees above the freezing point of water*. How is this remarkable change in climate to be accounted for? Geologists cannot much longer evade answering such questions as these.

[1] In the British Islands January 15 is reckoned the time of maximum cold, which is twenty-four days after midwinter.

[2] By this is meant the temperature of the upper layers of the atmosphere of place, which controls the radiation; this temperature varies with the latitude, and is probably always below zero Fahrenheit.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The Cambridge Museums are every year the scene of a large increase of work, new departments being continually added, even under the present conditions of impecuniosity. The annual reports recently issued on the condition and progress of all the departments testify to much excellent work. The death of Prof. Miller, who for forty-nine years occupied the Chair of Mineralogy, has brought a valuable bequest to the museum he presided over, in the shape of 300 volumes of books and many specimens and scientific instruments, including his famous goniometer and the physical apparatus, balances, thermometers, and barometers employed by him in his investigations for the restoration of the standards of weight. Prof. Lewis, who has succeeded to the Chair of Mineralogy, ably assisted by Mr. Solly, is cataloguing the museum, and already half the work is accomplished. Valuable specimens besides Prof. Miller's bequest have been added to the museum by purchase as well as by donation, including a small case of minerals belonging to the late Dr. E. D. Clarke, given by the Rev. B. S. Clarke, Boxted, Colchester. Prof. Lord Rayleigh's Apparatus Fund has reached 202*l.*, including 50*l.* from himself, which has been spent partly upon instruments required to be multiplied, in consequence of the increased number of students; but the additions during the year also comprise a large electro-magnet with heavy glass and nicol; a 2½-inch achromatic telescope; Joule's apparatus for investigating the maximum density of water; telephones and various optical apparatus, including new double refractive apparatus for combining prismatic colours. Many important pieces of apparatus have been made for the Cavendish Laboratory in Prof. Stuart's laboratory. Professors Liveing and Dewar report that with the 200*l.* alloted to them they have purchased several pieces of apparatus permanently useful in a variety of investigations. Prof. Stuart's department (mechanism) has progressed very considerably during the year. The apparatus, machines, tools, and materials in connection with the department have been recently valued at over 1500*l.*, of which only about 250*l.* is University property, the rest having been provided by the private enterprise of Prof. Stuart. In the Geological Museum, despite the want of suitable workrooms, Mr. Tawney has succeeded in arranging the petrological collection. Mr. Keeping reports the addition of many important fossil specimens both from England and America. Prof. Humphry reports further additions to the rich collection of human skulls under his charge. Mr. J. W. Clark, Superintendent of the Museum of Zoology and Comparative Anatomy, calls special attention to the beautiful coloured drawings of animals that cannot be preserved in spirit, or are too small to be seen without a microscope, added by Prof. A. C. Haddon, late Curator in Zoology. His successor, Mr. A. H. Cooke, Fellow of King's College, has commenced the work of determining and cataloguing the Woodward and Hepburn collections of shells. Mr. Clark has added a series of preparations showing the structure of the manatee, from a specimen presented by the Directors of the Brighton Aquarium. The very fine skeleton of the musk-ox brought home by the North German Polar Expedition of 1872 has been purchased. The skeleton of *Ceratodus Forsteri*, from the specimen presented by Prof. Liversidge, has been prepared in the museum. Many additions have also been made to the reptilian, ornithological, and other series. Dr. Michael Foster notes that his classes for histological work have become so large that a new bench, less convenient as to light, has been added. The numbers attending his courses are between sixty and seventy men and twenty women for the elementary classes, and fifteen men for the advanced classes. He remarks that his students would profit more if not so much harassed by striving to attend too great a number of lectures and courses. Prof. Babington records a large amount of herbarium work, including the naming of Gardner's collection of Brazilian plants, numbering 5000 specimens, presented by the professor. He has also obtained, at a very moderate cost, the entire collection of the late M. Gaston Genevier of Nantes, consisting of about 7000 species from France, Spain, Algeria, Asia Minor, &c., and all the typical specimens—over 500 in number—of the Rubi, described in his monograph of the genus Rubus. A proposal has been made by the Cambridge Philosophical Society to make their large and useful scientific library available for scientific students generally, and to allow it to be the nucleus of a much-needed library of science in the new museums, if the University will provide the salary of a librarian

for it. It is desired that this library shall be placed in a room vacated by Dr. Michael Foster's classes, and formed by the amalgamation of two old classrooms.

THE VICTORIA UNIVERSITY.—The Preliminary Examinations for the year 1881 will be held at the Owens College on June 20 and following days, and on October 5 and following days. Regulations:—1. Candidates for these examinations are required to present certificates of matriculation in the University. 2. The days fixed for matriculation are June 13 and 14, between the hours of two and four p.m., and October 1 and 3. 3. Students, on presenting themselves for matriculation, are required to furnish to the Registrar of the University certificates of admission as students of one of the colleges of the University, to pay a fee of 2*l.*, and to sign an undertaking to obey the regulations of the University. 4. The October Preliminary Examination is open only to students who have matriculated since the Preliminary Examination held in the previous June, or who failed in this examination, or were prevented attending it by reasons satisfactory to the General Board of Studies. Candidates are requested to communicate with the Registrar, Prof. Adamson, who will supply them with the detailed syllabus of subjects, regulations, and time-table for the examination.

ROYAL UNIVERSITY OF IRELAND.—The copy of the scheme for the organisation of the University as adopted by the Senate has now been laid, pursuant to Act of Parliament, before the House of Commons, and it has been, by order of that House, printed. It gives full details of the degrees to be granted, which are in Arts a Bachelor, a Master, and a Doctor of Literature degree; in Science a Doctor's degree; in Engineering a Bachelor and a Doctor's degree; in Law, Music, and in Medicine the same; in surgery a Master's degree, with a special diploma in Obstetrics and in Sanitary Science. All these degrees are open to persons of either sex. The examinations for women shall be held apart from those for men, but on the same days. Candidates for any degree must have passed the Matriculation Examination, which will be held not only in Dublin but at certain local centres. The examination will be held in the subjects of Latin, English, Elementary Mathematics, Experimental Physics, and in any one of the following languages: Arabic, Celtic, French, German, Greek, Hebrew, Italian, Sanskrit, or Spanish. Candidates must also pass a first University Examination, to which they will only be admitted after the lapse of one academical year from matriculation, the subjects for this being a more advanced course of that fixed on for matriculation. One year after this is passed the student in Arts may proceed to his second University examination, in which he will have his choice of a great variety of subjects, but Latin, Greek, and English on the one hand, or Mathematics on the other, are compulsory. At this stage of his career the student may select Biology, including Physiology, Botany, and Zoology, or Geology, and after the expiration of one more year he can proceed to his B.A. examination, for which he will be permitted to select either the Classics or Mathematics, with the selection of one other of a long list of subjects given. For the M.A. examination the candidate must be a B.A. of one year's standing at the least, and he may answer in any one of a selected group of subjects. The regulations for the degrees of Doctor of Literature and Doctor of Science are not yet matured. Twelve scholarships of 50*l.* each are to be offered each year for competition, four in Classics, four in Mathematics, and four in Modern Literature. Exhibitions varying from 100*l.* to 15*l.* will be given to Honour Men. There are to be forty-eight Fellows. The salary of a Fellow, if he be not also a Fellow or Professor of some other University or College attached to a University endowed with public money, shall be 400*l.* a year. If he be such, then he shall only receive so much as will bring his salary up to 400*l.* a year. These Fellows shall constitute a Board of Examiners. There shall be also fourteen junior Fellows, their salary to be 200*l.* a year. No Fellow or Professor of any other College or University is eligible, and the candidates must be Graduates of the Royal University of four years standing. All Fellowships are tenable for seven years. Thus if a senior Fellow be elected from an already endowed College, the chances are that while he will have to do his full share of the work, he will receive only as much salary as will bring his total emoluments to 400*l.* Thus a Professor of one of the Queen's Colleges (Belfast or Cork) if elected would only receive 5*l.* or 10*l.* a year, but if a Professor from the Catholic College in Dublin were elected, as it is not endowed, he could receive a full 400*l.* a year, and yet his duties would be —so far as the Royal University is concerned—the same as his colleague from the endowed College, who would receive almost no salary at all. Thus a scheme for endowing Colleges through the resources of the Royal University has been at last successfully carried out. The subjects and books for the various examinations appear to be most judiciously selected, and in many respects might teach a lesson to our older Universities. The Senate close their scheme by a request that provision may be made for securing for the University a proper Senate Hall, Examination Rooms, a Library, &c., and urge that these should be all built within the area of the City of Dublin.

ETON.—Mr. G. C. Bourne of Eton College has been elected to a Natural Science Exhibition of 50*l.* a year for four years at New College, Oxford, for proficiency in Biology. Mr. Bourne is one of the foremost athletes of his school, having rowed in the Eton crew at Henley Regatta for the last three years, as he will again in a few weeks' time. For the past two years he has filled the exalted but responsible post of "captain of the boats," but has nevertheless found time to devote himself successfully to his favourite study, and has gained new honours for his school in a field hitherto untrodden by Etonians.

SCIENTIFIC SERIALS

Journal of the Franklin Institute, April.—The wearing power of steel rails in relation to their chemical composition and physical properties (continued), by Dr. Dudley.—Experiments on the strength and stiffness of small spruce beams, by Mr. Kidder.—Observations on the water-supply of Philadelphia, by Mr. Haines.—A fourth state of matter, by Mr. Outerbridge, jun.—The moon of Earth and Jupiter, by Dr. Chase.

Bulletin de l'Academie Royale des Sciences de Belgique, No. 2.—Note on the determination of the longitude of Karema, by Capt. Cambier.—New data on the non-existence of pentathionic acid, by M. Spring.—On a new fossil fish of the environs of Brussels and on certain enigmatic bodies of the crag of Antwerp, by M. van Beneden.—On phosphate-beds in Belgium (third note), by M. Petermann.—On the theory of polars, by M. Le Paige.—On a new form of reddish frog from the south-east of France (*Rana fusca Honnorati*), by M. Héron Roger.—Study on the hypophysis of Ascidians and the neighbouring organs, by M. Julin.

Bulletin de l'Academie Imperiale des Sciences de St. Petersbourg, t. xxvii. No. 2.—Development of the absolute perturbations of a comet, by O. Backlund.—Champignons recently collected in Mongolia and Northern China, by C. Kulchbrenner and F. de Thümen.—Observations of Jupiter's spots, by M. Kortazzi.—On the oxidation products of erythrite, by S. Przybytek.—The money of the Ileks, ancient Khans of Turkestan, by B. Dorn.—Remarks on the group of the Pteroclides, by M. Bogdanoud.—Relations between isobars and isanomalies of temperature, by H. Wild.—Influence of pressure on the electric resistance of metallic wires, by O. Chwolson.—The Russian species of humble-bees in the collection of the Academy, by F. Monawitz.—On the value of errors depending on the retardation or prematurity of impulsions in Weber's methods for measuring instantaneous electric currents, by O. Chwolson.

Archives des Sciences Physiques et Naturelles, No. 4, April 14.—Study on the chemical composition of albuminoid substances, by Dr. Danilewsky.—Automatic methanometer, or automatic analyser of fire-damp, by M. Monnier.—Researches on vegetation, by Prof. Westmann.—Distillation and rectification of spirits by the rational use of low temperatures, by M. Pictet.—On phyllotaxy (continued), by M. de Candolle.

Rivista Scientifico-Industriale, No. 7, April 15.—Second reply in defence of the true theory of the siphon, by Prof. Marangoni.—Determination of the specific gravity of solids soluble in all liquids, by Dr. del Lupo.—Relation of the specific gravity and the pressure of saturated steam, by Prof. Ciccone.

THE last number of the Russian *Journal* of the Chemical and Physical Society (vol. xiii. fasc. 4) contains the following papers:—On the rate of chemical reactions, by M. N. Kayander.—On the influence of chemical structure on the refrigerating power of organic bodies, by M. J. Kanonnikoff.—On the laws of double decompositions, by M. A. Potilitzin.—On the chemical value of the constituents of alcohols, by Prof. Mensbutkin.—On ice under "critical pressure," by Prof. Boutleroff.—On electricity of con-

tact, by MM. Stoletoff and Sokoloff.—On the influence of pressure on galvanic resistance, by M. Khwolson.—On dynamo-electric machines without iron, by M. Latchinoff.—On the voltaic arc, by M. Sloughinoff.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 12.—"Physiological Action of β Lutidine." By Greville Williams, F.R.S., and W. H. Waters, B.A.

Up to the present the authors' investigations have chiefly related to the action of this poison upon the heart and central nervous system of the frog.

Various methods were used to study its effect upon the heart, and each gave most distinct results pointing to an increase of the tonicity. After the introduction of a small quantity of β lutidine into the system, stimulation of the vagus failed to cause a cessation of the heart's beat.

In frogs retaining their spinal cord the injection of the alkaloid removed all powers of reflex action, which removal the authors proved by other experiments to be due to the β lutidine acting on the reflex centre. The alkaloid was found to be antagonistic to strychnine: removing strychnine-tetanus when injected after that alkaloid and preventing its appearance when injected beforehand.

Chemical Society, May 19.—Prof. Roscoe, president, in the chair.—The following papers were read:—On ammonium nitrite and the reaction between hydrogen and nitric oxide in the presence of spongy platinum, by L. T. Wright. The author has repeated the experiments recently made by G. S. Johnson, who stated that the synthesis of ammonia was effected by passing hydrogen and nitrogen over heated spongy platinum. The author states that the nitrogen was contaminated with nitric oxide. The substance used by Johnson—ferrous sulphate solution—for freeing the nitrogen from nitric oxide does not completely absorb that gas. When pure nitrogen obtained by the action of potassium hypobromite on ammonium chloride, or by passing the nitrogen evolved by heating ammonium nitrite through an alkaline sulphite, was used no ammonia was formed. Hydrogen reacts upon nitric oxide in the presence of cold spongy platinum to form ammonia.—On the synthetical production of urea from benzol, ammonia, and air by the action of heated platinum, by E. F. Herroun. The author has aspirated air through benzol and ammonia, and then passed the mixed vapours over a heated spiral of platinum wire. Urea was formed, which was identified by its reactions and analysis. Acetylene can be substituted for benzol vapour.—On a proposed volumetric method for the ready estimation of a soluble sulphite and free sulphurous acid, or of free sulphurous and sulphuric acids even in the presence of sulphates, by O. V. Pisani.—On the identification of crystallised alkaloids by the microscope, and the use of polarised light, by A. Percy Smith.—On the colour-properties and colour-relations of the metals of the iron-copper group, by T. Bayley. The author continues in this paper his investigations as to the quantities of cobalt and nickel, or of cobalt, copper, and iron, which, when mixed as sulphates, produce colourless grey solutions.—On the effects of the growth of plants on the amount of matter removed from the soil by rain, by E. W. Prevost.—On the action of sodium on cinnamic ether, by F. Hatton.

Physical Society, May 14.—Prof. Fuller in the chair.—New Members: Mr. D. J. Blakely and Mr. Walter Kilner.—Prof. G. C. Foster read a communication from Prof. Rowland and Mr. E. H. Nichols of Baltimore, U.S., on electric absorption in crystals. According to the theory of Clausius, Maxwell, and others there should be no electric absorption in the case of perfectly homogeneous substances. Prof. Rowland tested this deduction in the case of glass, which is not quite homogeneous, quartz, and calcite. This was done by placing the material as the dielectric in a condenser formed of two amalgamated copper plates. The condenser was charged by six Leyden jars, and the absorption measured by a quadrant electrometer. The results were that quartz had about one-ninth the absorptive power of glass, and calcite none at all. Dr. Hopkinson said that the *kind* of glass was important, and threw doubts on the theory that the absorption was due to heterogeneity; paraffin wax had little absorptive power, and yet was very heterogeneous. Professors Perry and Ayrton thought that two non-homogeneous substances in combination might have no residual charge. Mr. Lewis Wright suggested that the optical character of crystals should be considered in these experiments, which might be extended to other crystals. Calcite is uniaxial.—Prof. Minchin, of Cooper's Hill, Engineering College, described his new absolute sine electrometer. This consists of two metal plates, in one of which is an aperture nearly closed by a metal trap-door suspended from the plate by two fine platinum wires, and resting against fine stops, when the plates are hung vertically. These plates are connected to the poles of the cell to be measured, and tilted out of the vertical till the attraction of the whole plate on the suspended trap or shutter is just balanced by the weight of the latter. The electromotive force is then proportional to the sine of the angle of displacement. Dr. Lodge remarked that the apparatus combined sensitiveness with practicability. The E.M.F. of a single cell could be measured by it, whereas Thomson's absolute electrometer could only give the total of a number of cells. Prof. Ayrton stated that he and Prof. Perry hoped to modify the instrument in the direction of sensitiveness by adding another plate and giving it a high charge. Dr. Coffin suggested reversing the process of taking an observation.—Prof. Foster read a paper by Dr. J. E. Mills, on the ascent of hollow glass balls through liquids. A glass ball of a pear shape rises through a liquid with a sensibly uniform velocity, which varies with the liquid. The time of ascent is proportional to the square of the diameter of the vessel, and depends of course on the specific gravity of the contents of the bulb. Dr. Mills measures the density of gases and liquids in this manner. Prof. Perry thought that the bulb should be of a shape having no re-entrant angles.

Geological Society, May 11.—R. Etheridge, F.R.S., president, in the chair.—Joseph Deeley, George Kilgour, Griqualand West, South Africa, and Roderick William MacLeod were elected Fellows of the Society.—The following communications were read:—Notes on the fish-remains of the bone-bed at Aust, near Bristol, with the description of some new genera and species, by James W. Davis, F.S.A., F.G.S. The fossil fishes described in this paper are from the Rhætic bed at Aust Passage. The fishes belong to the orders Plagiostomi and Ganoidei, some of the former being of considerable size. It is inferred, from the intermixture of Saurians and fishes, that the deposit is the result of shallow water existing near land, in which the fishes lived and the Saurians occasionally disported themselves. Besides the fossil remains of the animals which lived during the deposition of the Aust-beds, there are also others which appear to have been derived from the Mountain Limestone and the Coal-measures, representing such genera as *Psammodus*, *Psephodus*, *Helodus*, and *Ctenoptychius*.—On some fish-spines from the Coal-measures, by J. W. Davis, F.S.A., F.G.S.—The author described in this paper three species of a new genus of fossil fish from the Carboniferous formation, two of the species having been found in the Cannel coal of the West Riding of Yorkshire, and the other in the Burghlea limestone, near Edinburgh. *Anodontacanthus* is a straight spine, offering many points of resemblance to some of the Pleuracanths; it has a similarly close-grained microscopical structure, the internal cavity opens terminally at the base of the spine, and it was not deeply implanted in the flesh of the fish. It however differs from all the Pleuracanths in being quite free from external denticles; its surface is plain or but slightly striated, whilst that of *Pleuracanthus* always possesses a double row of denticles either ranged laterally along the exposed part of the spine or in some position between the lateral and posterior aspects of the spine. It is possible that evidence may be discovered which will render necessary the removal of these spines to the genus *Pleuracanthus*; but at present there is no evidence that such is advisable. All the specimens of *Pleuracanthus*-spine found associated with teeth or shagreen have been armed with the double row of denticles, and at present no evidence exists that spines without denticles were associated with remains of this genus. It is therefore considered best to institute a new genus for the three species with the name *Anodontacanthus*, in allusion to its having no teeth or denticles.—On some specimens of *Diastopora* and *Stomatopora* from the Wenlock limestone, by Francis D. Longe, F.G.S. Mr. Longe showed and described some specimens of Bryozoa from the Wenlock limestone of Dudley, which he compared with corresponding forms from the Oolites and later periods, and pointed out the close similarity of the Silurian with the later forms, in respect of the shape and dimensions of the cells, as well as in the habit of cœnœcic growth.—On a new species of *Plesiosaurus*

(*P. Conybeari*) from the Lower Lias of Charmouth, with observations on *P. megacephalus*, Stutchbury, and *P. brachycephalus*, Owen, by Prof. W. J. Sollas, M.A., F.R.S.E., F.G.S., &c., Professor of Geology in University College, Bristol; accompanied by a supplement on the geological distribution of the genus *Plesiosaurus*, by G. F. Whidborne, M.A., F.G.S. The greater part of this paper was devoted to the description of a remarkably fine specimen of *Plesiosaurus* from the *Ammonites obtusus* zone of the Lower Lias, Charmouth. For the species the name of *P. Conybeari* is proposed. *P. Conybeari* agrees closely with *P. Etheridgii* in the relative length of head and neck; but it has eight more cervical vertebræ than the last-mentioned species. In the number of the cervical vertebræ it agrees with *P. homalospondylus*, but has a much larger cervico-cephalic index.—On certain quartzite and sandstone fossiliferous pebbles in the drift in Warwickshire, and their probable identity with the true Lower Silurian pebbles, with similar fossils, in the Trias at Budleigh Salterton, Devonshire, by the Rev. P. B. Brodie, M.A., F.G.S.

Institution of Civil Engineers, May 10.—Mr. Brunlees, F.R.S.E., vice-president, in the chair.—The paper read was on torpedo boats and light yachts for high speed steam navigation, by Mr. John Isaac Thornycroft, M.Inst. C.E.

Meteorological Society, May 18.—Mr. G. J. Symons, F.R.S., president, in the chair.—D. W. Barker, B. Jumeaux, W. Oelrichs, H. Porter, W. Roper, and Rev. G. R. Wynne were elected Fellows of the Society.—The following papers were read:—Comparison of Robinson's and Osler's anemometers, with remarks on anemometry in general, by Richard H. Curtis. The author in this paper gives a very clear statement of the present state of anemometry, and points out the defects in Osler's and Robinson's anemometers, which are the chief forms of recording instruments used in this country.—Notes on waterspouts observed at Cannes in January or February, 1872, by the Hon. F. A. Rollo Russell, M.A.—On some Swedish meteorological observations in connection with the return of the seasons, by Alexander Beazeley, M.Inst.C.E.

PARIS

Academy of Sciences, May 16.—M. Wurtz in the chair.—The following papers were read:—Meridian observations of small planets at the observatories of Greenwich and Paris during the first quarter of 1881, communicated by M. Mouchez.—Nebulæ discovered and observed at the Observatory of Marseilles, by M. Stephan.—On the supposed presence of Proteaceæ of Australia in the flora of ancient Europe, by M. de Saporta. He gives reasons for doubting the supposed relation of the fossil plants, and the anomalous direct implantation in the heart of ancient Europe of a whole colony of plants that are now confined to a region in the southern hemisphere.—M. Berthelot presented the second edition of his "Traité élémentaire de Chimie organique" (which is about double the first).—Report on a memoir of M. Graeff relative to a series of experiments at the Furens reservoir on outflow of water.—On the transformation of morphine into codeine and homologous bases, by M. Gremaux. Codeine he regards as a methylic ether of morphine, considered as phenol. He transforms morphine into codeine by heating it with alcoholic potash or soda and iodide of methyl. Using ethylic iodide, a new base is got, homologous with codeine; indeed a series of these *codeins* (as the author calls them) may be had, as numerous as the series of ethers of an alcohol.—On the most ancient reptiles found in France, by M. Gaudry. He presented a fine specimen of remains of *Stereorachis dominans*. By their enlarged ribs, the arrangement of the thorax, the scales with spines, and especially the characters of the humerus, the Permian reptiles of France (like some fossils of South Africa, studied by Prof. Owen), somewhat lessen the wide interval between reptiles and monotremata mammalia. They have traits of resemblance to reptiles of the Trias, and to those of the Permian in the United States, studied by Mr. Cope.—Observations on Swift's comet at Marseilles Observatory, by M. Borrelly.—On the separation of roots of numerical equations, by M. Laguerre.—On the principle of conservation of electricity, by M. Lippmann. The principle is expressed by a condition of integrability. In the memoir the author's method of analysis is applied to various phenomena—dilatation of glass of a Leyden jar during charge, electrisation by compression of hemihedral crystals, and pyroelectricity of crystals. The existence and law of certain new phenomena, not yet verified, are deduced.—On a mode of graphic representation of phenomena produced in dynamo-electric machines, by M. Deprez. A curve, called the characteristic of the machine, is got thus: Communication being first broken between the ring and the exciting electro-magnets, a known current, from an external source, is sent through the latter. The ring is then rotated with a given velocity; then the difference of potential between the two extremities of the (broken) induced circuit is measured. The [auxiliary current is varied, and its intensities are taken as abscissæ; the ordinates are the differences of potential of the ends of the induced circuit.—On the theory of rotatory polarisation, by M. Mallard.—On the hydrates formed by chloride of calcium, by M. Lescœur. He recognises the existence of $CaClHO$, of $CaCl_2HO$, of $CaCl_4HO$ (only under 129°), and of $CaCl_6HO$ (under 65°).—On the solubility of mercurous chloride in hydrochloric acid, by MM. Ruyssen and Varenne.—Peptones and alkaloids, by M. Tanret.—On the non-existence of *Microzyma cretæ*, by MM. Chamberland and Roux. The Meudon chalk behaves like chalk sterilised by heating, and contains nothing capable of producing microscopic organisms or any fermentation; thus M. Béchamp's observations (1866) are controverted.—On the crystallisation of alums, by M. Loir. The different faces of a crystal have not the same attractive power towards the solution of the substance employed to feed it.—Phyllotaxy, by M. Baron.—Studies on the coal formation of Commentry, by M. Fazol. He supposes that all the materials of this formation have been carried by water and deposited in a deep lake during a tranquil geological period.—On the milch sheep, by M. Tayon. There is an inverse correlation between the production of wool and that of milk. The presence of hairs directed upwards on the teats and neighbouring parts is noticed.—On the alterations of milk in sucking bottles, ascertained along with the presence of a cryptogamic vegetation in the caoutchouc tube fitted to the glass bottles, by M. Fauvel. Of thirty-one sucking-bottles examined in the crèches, twenty-eight contained this cryptogamic vegetation.

ARCTIC ECHINODERMATA

A Memoir on the Echinodermata of the Arctic Sea to the West of Greenland. By P. Martin Duncan, F.R.S., and W. Percy Sladen. Pp. 82, Six Plates. (London: Van Voorst, 1881.)

MESSRS. DUNCAN AND SLADEN will receive the thanks of zoologists for the publication of this memoir, which will owe its importance as much to the care with which it has evidently been prepared, as to the interest of the group with which it deals, and the value that it has in being a monograph of a definite zoological region. The time would, indeed, seem to have come when no further question is possible as to the existence of a characteristic circumpolar fauna; nearly ten years ago Prof. Alex. Agassiz directed attention to the wide distribution of that common form, which has unfortunately so very long a name, the regular Echinid—*Strongylocentrotus drobachiensis*, in his "Revision of the Echini," and the researches of Mr. Seebohm have led him to a similar conclusion as to the circumpolar distribution of Birds. Further evidence is given by the present authors, who sum up the matter thus:—

"When these details are carefully considered, it becomes evident that each one of the great groups of Echinodermata tells the same story regarding distribution. The fauna, as a whole, is not an extension northwards of species from more temperate climates, but is essentially circumpolar."

Where the range is so wide considerable variations are to be expected in the characters of the species, and we feel inclined to attach as much importance to the accounts which the authors give of the variations they have been able to observe as to their technical zoological definitions of the species. We have been unable to find in the memoir any notice of the number of specimens which were accessible to the authors, but we believe it was quite large enough to have made the account of varietal forms a necessary part of a complete account.

It was, at any rate, large enough to make the number of new species very small; a new *Antedon*, a new member of Sars' interesting genus *Pedicellaster*, to which Mr. Sladen has given the appropriate name of *palæocrystallus*, make up, with an Ophiurid described by Prof. Duncan, the sum of our gains in that direction. So striking were the characters of this Ophiurid that it was found necessary to form a new genus for its reception; curiously enough Dr. Duncan proposed a generic term—*Luetkenia*—which has already been twice used in zoology; but this was a matter of slight importance, as Messrs. Koren and Danielssen had the priority in recognising the generic distinction of the Ophiurid in question, and of giving it the name of *Ophiopleura*. This priority was however merely a matter of months, and not of years, as the English naturalist would lead us to imagine by leaving uncorrected in his proof the date of 1867 for 1877 (see *tom. cit.* p. 54). Dr. Duncan holds to the view he expressed in 1878 that the form has affinities with *Amphiura* and *Ophioglypha;* what Prof. Lyman's views are it is impossible to state very definitely, but from the position which he has given to *Ophiopleura* in his lately-published "Preliminary List," it would seem that he attaches greater importance to its Ophioglyphan than to its Amphiuran characters.

We are not quite sure that we should agree with some of Mr. Sladen's views on nomenclature; but it is, we fear, too late now to raise a protest against the use of the term *Asteracanthion;* as the genus to which the name is applied has some eighty constituent species, it would be a matter of satisfaction if of the parties who use *Asteracanthion* or *Asterias* one or other would yield to the arguments adduced by the others. We must confess that for ourselves the latter term appears to have every advantage both of right and of convenience over the more unwieldy title of Müller and Troschel. It is much more satisfactory to direct attention to the way in which the authors have grappled with an old and unknown synonym in the case of *Astrophyton Agassizii*. In the year 1819 Dr. Leach applied the specific term *arcticus* to a specimen of "*Gorgonocephalus*" brought home by Sir John Ross; the definition of this species was too ambiguous and short for practical purposes, and it was not until Stimpson described the Invertebrates of the Grand Manan that the Arctic form got the name by which it has since been called by every naturalist who has had occasion to mention it; Lyman, Verrill, Ljungman, Lütken and Norman have all known it as *Astrophyton Agassizii*. The specimen which is supposed to be the type of Leach's description has no title attached to it, or any known history; in other words, it can never be *known* what Leach meant to describe, though it is easy enough to *guess;* under these circumstances (by detailing which the authors take, as we hope, the wind out of any mere bibliographer's sails), "we do not feel justified in restoring Dr. Leach's name."

This is an eminently satisfactory conclusion; ill-drawn definitions and unlabelled or wrongly-labelled specimens have had their day, and a good long day has it been, in hampering the progress of a growing science; if zoology is to advance with the other branches of biology, a purist sense of justice must not step in and lead us continually away from the real business of natural history to the dryasdust occupation of elaborating synonymical lists. A dictator-speaker and some rules of urgency might well be invented in the interests of zoological progress.

The six plates, on which twenty-six of the thirty species described in this volume are carefully figured, make a very useful addition to a work which the Government Grant Fund of the Royal Society were fully justified in subsidising.

F. J. B.

GREEK GEOMETRY

Greek Geometry, from Thales to Euclid. Part II. By G. J. Allman, LL.D. Extracted from "Hermathena," Vol. iv. No. vii. 49 pp. (Dublin: University Press, 1881.)

IN NATURE, vol. xviii. p. 291, we briefly referred to the first part of Dr. Allman's work, which gave an account of the earlier geometers, more especially treating of the labours of Thales and Pythagoras. The opening years of the fifth century before the Christian era were very dark ones for Greece, but "then followed the glorious struggle. . . . A solid basis was thus laid for the development of

Greek commerce and for the interchange of Greek thought, and a brilliant period followed—one of the most memorable in the history of the world." Athens became the centre of all intellectual movement. To her—the Athens of Pericles—came Hippocrates of Chios, and "in this city geometry was first published."

Our author agrees with Hankel (against Proclus) as to the important influence of the Eleatics (Parmenides and Zeno), "not only on the development of geometry at that time (circ. 450 B.C.), but further on its subsequent progress in respect of *method*." Clairaut, in his "Elements of Geometry" (recently translated by Dr. Kaines, the original text is cited by Dr. Allman), notices this influence in the case of Euclid. The paradoxes of Zeno led to the banishment of the Infinite (which plays so important a part in the modern treatment), "the infinitely small as well as the infinitely great." What Hippocrates may very fairly be supposed to have done in relation to the squaring of the circle is, we think, well put. "Simplicius has preserved in his 'Comm. to Phys. Ausc.' of Aristotle a pretty full and partly literal extract from the 'History of Geometry' of Eudemus." It is to Bretschneider we owe a careful revision and emendation of this fragment, and our author has skilfully attempted to determine what is Simplicius and what is simply Eudemus in this account. It is curious that Bretschneider merely notices the "circumstantiality of the construction and the long-windedness and the over-elaboration of the proofs," and Hankel expresses surprise that this fragment, "150 years older than Euclid's Elements, already bears that character, typically fixed by the latter, which is so peculiar to the geometry of the Greeks." Had the present pamphlet been confined to the elucidation of this single matter it would have had a sufficient *raison d'être*.

The next geometer whose contributions to geometry are determined and discussed is Democritus, more usually regarded as a philosopher. At this stage, too, our author takes stock, and shows that the progress made in this (about) half-century interval since Pythagoras mainly "concerns the circle."

We note the connection of the name of Hippocrates with another of the famous problems of antiquity, viz. the duplication of the cube: he seems to have been the first to reduce this question to the finding of two mean proportionals between two given straight lines, the greater of which is double the less. Many interesting particulars are given in connection with this problem. The general problem is stated to have been first solved by "Archytas of Tarentum, then by his pupil Eudoxus of Cnidus, and thirdly by Menæchmus, a pupil of Eudoxus"; this last used "the conic sections which he had discovered." A third problem, the tri-section of an angle, also came to the front about this time. Dr. Allman fully discusses this also, and shows that it was one which was fairly within the reach of a Pythagorean. Montucla however attributes to Hippias of Elis, a contemporary of Socrates, the invention of the quadratrix (the quadratrix of Dinostratus), by means of which (in a quite different way from Sylvester's Fan) an angle can be not only trisected, but divided into any number of equal parts. Allman sides with Hankel and shows the improbability of Hippias being the inventor, but he is against him when he refers the method of exhaustions to Hippocrates of Chios. It will have been seen that the great geometer of this period is Hippocrates, "who seems to have attracted notice as well by the strangeness of his career as by his striking discovery of the quadrature of the lune." The unfavourable statements of Aristotle, Eudemus, Jamblichus, and Eutocius are examined, and part of the summing up is, "We may fairly assume that Hippocrates imperfectly understood some of the matter to which he had listened; and that, later, when he published what he had learned, he did not faithfully render what had been communicated to him."

An examination of this pamphlet still further shows that the writer, while carefully using the recent works of Bretschneider, Hankel, Cantor, and others, has himself gone over the original authorities and formed his own opinions upon the difficult questions that turn up. It is, in our opinion, a most valuable contribution to the subject, and we shall be glad when the piecemeal work in "Hermathena" is done, and the book appears, as we believe it is the writer's intention that it should appear, in proper book form as one work.

OUR BOOK SHELF

The Zoological Record for 1879. Being Volume Sixteen of the Record of Zoological Literature. Edited by Edward Caldwell Rye, F.Z.S. (London: John Van Voorst, for the Zoological Record Association, 1881.)

THE editor's promise to the members of the Zoological Record Association has been kept, and the *Record* for 1879 was published in the month of April in this year. We gladly note in addition his confident expectation that the *Record* for 1880 will be published ere the present year ends. This sixteenth volume contains nearly 700 pages of well-condensed records of the literature of zoology of 1879. The lion's share of the hard work has fallen to Mr. W. F. Kirby, who, with Mr. McLachlan, records the literature of the Insecta. The Rev. O. P. Cambridge gives the record of the Arachnida for 1878 and 1879. The Vermes and Echinoderms are done by Prof. Jeffrey Bell, and the Cœlenterata and Protozoa are elaborated by A. G. Bourne, S. J. Hickson, and Stuart Ridley. The works on the Mammals are recorded by W. A. Forbes; on the Birds by Howard Saunders; on the Reptiles and Fishes—alas! that we should have to write it—by the late gifted A. W. E. O'Shaughnessy. Prof. E. von Martens still records the literature of the Mollusca and Molluscoidea, the only recorder still remaining as such of that small group who came to the assistance of Dr. Günther in 1864. We miss from last year's list of recorders Dr. C. Lütken, who served during his seven years well and faithfully; in him knowledge and experience of the subject he worked at were combined with much tact. The British Association, the Royal Society, and the Zoological Society of London have, as is now usual, handsomely assisted in aid of the publication of this most useful volume.

The most useful index to new genera and sub-genera seems most carefully done. The list of new genera is for the year almost 1000; so that evidently the zoological kingdom is not as yet worked out.

Wiltshire Rainfall, 1880. (Marlborough: C. Perkins and Son, *Times* Office).

THE compilers of this carefully-printed and, for the class of publications, luxuriously got-up annual merit our hearty commendation for the general excellence of the work thus put before us. From its physical geography Wiltshire forms a well-marked rainfall region, it being a little to the north of the centre of the county that the two Avons and several tributaries of the Thames take their rise. From this plateau the country slopes northward to the

Upper Thames, eastwards along the Kennet, southwards to Salisbury, and westwards along the North Avon. The rainfall of this region is now observed at twenty-eight stations, and the daily amounts are printed *in extenso*, and the eye readily notes the maximum monthly fall at each station, these being printed in thicker type. On each monthly sheet the means of the previous ten years' observations are given for the ten stations at which observations have been made for the whole of that period. The mean annual rainfall of these stations for the past eleven years is 32·14 inches, the monthly maximum being 3·49 inches in October, and the minimum 1·82 inches in March. As contrasted with the more strictly central districts of England, the summer rainfall is relatively less, and the autumnal and winter rainfalls greater; and as contrasted with places more open to the Atlantic to west and south-westward, the rainfall is relatively greater in summer and less in winter. At seventeen stations observations have been made for at least six years, at which, if the averages be struck for the eleven years, differentiating where necessary, the largest mean rainfall is seen to be 40·32 inches at Corsham, near the summit of the long ridge separating the North Avon from its tributary Box Brook, and the smallest 29·76 inches at Pen Hill in the north on the high ground between the Thames and its tributary the Cole; —the former being one of the heights most open to winds from the Atlantic, and the latter one of the most sheltered heights from these winds. As regards annual amount and variation with season and configuration of surface, the rainfall of Wiltshire curiously resembles that of Deeside, Aberdeenshire. An excellent map showing the stations and their heights and the physical features of the county accompanies the Report.

Pheasants: their Natural History and Practical Management. By W. B. Tegetmeier, F.Z.S. Second Edition, greatly enlarged. (London: *The Field* Office, 1881.)

MR. TEGETMEIER is so well known as an authority upon pigeons and poultry of all kinds that everything which he writes on the subject of these birds is sure to be received with attention, and it is therefore scarcely a matter of surprise that a second edition of his well-known "Pheasant" book should have been called for. The work will be found invaluable to any one projecting the cultivation of pheasants either in the covert or in the aviary. After a brief review of the habits of pheasants in a wild state, the author gives ample information as to their management in preserves and in confinement, and also discusses the much-vexed question of the gapes and other diseases to which these birds are subject. The second portion of the work is devoted to the natural history of the common pheasant and its allies which are suitable for introduction into our woods, and also treats of the more gaudily-coloured Golden Pheasant, Monâl, and other species adapted for the aviary. Valuable experiences of the rearing of these birds and their habits in confinement are given by Mr. Tegetmeier, who seems to have spared no pains to make his book interesting and instructive. The illustrations have been executed on wood by the well-known artist Mr. T. W. Wood, who has evidently studied the birds in a state of nature; and although the plumage of the pheasant family does not lend itself readily to this style of illustration, the attitudes of most of the birds are happily rendered, while some of the figures representing the "showing off" of the male birds are excellently conceived.

Nach Ecuador. Reisebilder. Von Joseph Kolberg, S.J. Zweite vermehrte Auflage, mit einem Titelbild, 140 Holzschnitten und einer Karte von Ecuador. (Freiburg-im-Breisgau: 1881.)

THE Archbishop of Quito proceeded to Rome in 1869 to attend the meeting of the Vatican Council, and he bore with him a commission from Don Garcia Moreno, President of Ecuador, to obtain powers to establish a Polytechnic School and College for the Republic. As a result he sent to Quito, in 1870, two Germans and one Italian, members of the Society of Jesus, who should lay the foundation-stone of the establishment, and in 1871 Joseph Kolberg, the author of this quarto volume, followed. The murder of President Moreno in August, 1875, gave a death-blow to the new institution. During the five years of his sojourn in the country Kolberg had been in the habit of sending home notes of his various tours, sketches of the manners and customs of the people he met with, and this in a somewhat methodic manner, as might be expected from a professor of the higher mathematics. These notes and sketches were published from time to time in a publication called *Stimmen aus Maria-Loch*, and they embraced among others an account of the voyage out, of a visit to Chimborazo, and an account of the catastrophe of Havra (1868), and incidental to these latter chapters the author introduces a theory of volcanic eruptions which he evidently thinks the best fruit of his visit to Quito. All these varied sketches and others on the natural history and geography of the country were, at the "request of friends," re-published in one handsome illustrated quarto volume, which was indeed to have been dedicated to President Moreno, but is now dedicated to his memory. The first edition was edited by the author's friend, R. Cornelly, S.J., and was published in 1876. The present edition, which has been corrected and enlarged throughout, has been published under the author's own superintendence. Some of the wood engravings are new and interesting; others, such as those representing the flying-fish and the Coral Island, have well served their generation.

Second Report of the United States Entomological Commission for the Years 1878 and 1879. With Maps and Illustrations. 8vo, pp. 322, and Eight Appendices, pp. 74. (Washington: Government Printing Office, 1880.)

THIS Report of the three Commissioners (Prof. Riley, Dr. Packard, and Dr. Thomas) appointed to investigate the ravages of the "Rocky Mountain" and other locusts forms a handsome volume, got up in the exhaustive and elaborate manner so marked in all the U.S. Government publications. It is exceedingly difficult to give an adequate notice in a short space, on account of the varied nature of the subjects touched upon. Our readers will gather from this remark that "Economic Entomology" in the proper sense of the term by no means occupies the entire volume, nor is it entirely confined to the "Rocky Mountain" pest in particular. A large portion is occupied by an elaborate investigation of the habits of migratory locusts in all parts of the world, gathered from a host of publications, some of them of ancient date. The connection of meteorological influences with the migrations and development of North American locusts is fully examined. Chapters IX. to XI. treat on the anatomy of the locust, and form valuable contributions to the anatomy of insects in general, such as one would scarcely expect to find in a report of this nature; of these Chapters IX. and XI. are by Dr. Packard, and treat of the air-sacs and brain respectively: X. is by Mr. Minot, on general histology: these are illustrated by excellent plates. The "economic" chapters are more especially by Messrs. Riley and Thomas, and go exhaustively into the question, more especially as to attacking the insect in its breeding-places, experience proving that war waged against the migratory swarms is comparatively useless; in connection with this, suggestions of a very broad nature are made. The Government is advised to encourage settlement of waste lands and the making of railroads conducing thereto, to induce broad schemes for irrigation, to guard the present timber, and encourage the planting of forests, to effect judicious burning in the breeding-grounds, covering about 400,000

square miles as now estimated, to institute efficient systems of observations and warnings, &c., &c. Prof. Riley treats on the natural enemies of the locust, and illustrates the chapter by a remarkably well-executed plate. The general conclusion arrived at is that the evil may be materially modified, although utter extermination is out of the question.

The lengthy appendices give replies to the official circular from those interested, in widely-separated districts, often showing great practical and frequently scientific knowledge, sometimes combined with the illogical conclusions at which agriculturists often jump. Then there is list of species of locusts, &c., collected in the Western States in 1877, with descriptions of new species, worked out by Mr. Scudder; the plate illustrating this is not so good as usual, and scarcely sufficient for scientific purposes. A general bibliography of locusts (chiefly compiled by Mr. B. Pickman Mann), from 1542 forwards, must have occasioned great labour, and is correspondingly valuable. Other appendices treat on the flight of locusts (translated from the Italian); on a journey to Utah and Idaho, by Dr. Packard; and a translation of Yersin's researches on the function of the nervous system in Articulates. The six large folded maps on thick paper seem to be admirably adapted to illustrate the points to which each is directed.

We do not think it is pretended that some of the most useful chapters from a scientific point of view have any special, or even indirect, bearing upon the subject of Economic Entomology. The investigation of a locust's brain, for instance, will hardly reveal the mental condition of the insect, and show us why it is prompted to migrate or be so maliciously inclined towards destroying the hopes of the agriculturist. We prefer to regard these portions of the report as an outcome of a liberal endowment of research, the application of which to the nominal subject for inquiry is not too rigidly enforced.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Laurentian Gneiss of Ireland

ALLOW me to state that since writing the notice which appears in NATURE (vol. xxiv. p. 81), I have found that white crystalline marble has been described by Sir R. I. Murchison and Prof. Geikie as occurring in the Laurentian gneiss of Loch Maree, in Scotland. I had overlooked this statement, and was under the impression that limestone was absent from the Scottish Laurentian area. Its occurrence in both countries constitutes an additional point of resemblance. EDWARD HULL

Geological Survey of Ireland, May 31

Resonance of the Mouth-Cavity

WILL you give a place in NATURE to the inclosed letter which has just reached me? The writer is an organist and teacher of music of great repute in the North of England. The experiments which he describes will, I believe, interest many of your readers as much as they do me.

Trinity College, Cambridge, May 20 SEDLEY TAYLOR

MY DEAR SIR,—Travelling the other day by express from Scarborough to London, I found myself unconsciously moving my lips as if whistling a tune, which however I was not actually doing. Without any other action than the simple movement of the lips, I very distinctly heard different sounds in my mouth. Persevering in the practice of this discovered power of producing sound, I soon accomplished a fairly satisfactory performance—audible only to myself—of "Home, sweet home."

As soon as the train came to a standstill I found myself powerless to repeat the performance, for there was then no response to the contortions which by this time had attracted the attention of my fellow-passengers, who doubtless thought that I was being conveyed to a lunatic asylum. On resuming our former speed the "power of sound" once more responded to my efforts.

At once I perceived that I had made a discovery of which I had never heard or read in any of the numerous works on acoustics that I have studied. I perceived that I could single out different sounds from the noise of the train by a simple alteration of the size of the resonance-cavity of my mouth.

On my return home it occurred to me that the force of vibration in the air from the note of a harmonium might be able to set up a sympathetic resonance of the mouth. To my delight I found that I was right.

It is known that if a tuning-fork of proper size be held to the open mouth the latter can be so shaped as to give a powerful resonance; but I believe it is not known that the mouth for *any* sound (above about middle C to f''' or g''') is able to give a very distinct resonance.

Further experiments showed me that not only can the primes of notes within this limit be heard, but that any of these sounds are very clearly heard when they are upper partials of low notes.

This can be tested at the harmonium. Holding down, say, G on the first line of the bass, the third and following partials up to about the fifteenth, can be most clearly heard. The same held good when I experimented with men's and boys' voices.

But the most striking results were obtained at the organ. Holding the low C of the 8 ft. trumpet, the partials from e'' to $f\sharp''$ were most bright and clear. Other stops, according to their several qualities, yielded corresponding results. I tried in vain however to obtain resonance for a differential and summational tone.

When the upper partials of a compound sound are generated in the mouth, the sounds are so near that with careful adjustment beats come out very clearly.

It is well however to observe that the force or weakness of any single sound thus obtained depends greatly upon the distance from the source. JOHN NAYLOR

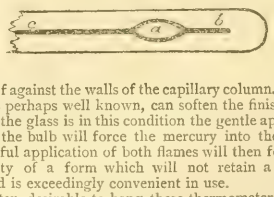
Scarborough, May 13

Suggestion Relating to the Kew Standard Thermometers

I SHOULD like to suggest, through your columns, two slight changes in the manufacture of the Kew standard thermometers, which I think will commend themselves to any observers who often have occasion to use these beautiful instruments.

1. The calibrating chamber at the top of the thermometer is now made as in the figure, where $c\,a\,b$ is the capillary column which expands at a into the calibrating chamber. Instead of being rounded off at d the capillary column is continued a short distance to b. This causes serious inconvenience in the transportation of the instrument, or in its calibration, because a small particle of mercury readily detaches itself from that in the chamber a, and once in b with a cushion of air between it and the remainder of the column, nothing but heat will dislodge it.

It does not require very great skill on the part of the glass-blower to form the chamber a by means of the pressure of the



mercury itself against the walls of the capillary column. The glass-blower, as is perhaps well known, can soften the finished tube at a, and while the glass is in this condition the gentle application of the flame to the bulb will force the mercury into the part at a, and the careful application of both flames will then form a pear-shaped cavity of a form which will not retain a particle of mercury, and is exceedingly convenient in use.

2. It is often desirable to hang these thermometers in a comparator or other place, and it would facilitate this if a glass ring were attached to the upper end, as is the case with the ordinary chemical thermometers. It is to be observed that the plane of this ring should be parallel to the enamelling in the tube.

It is often convenient to know the kind of glass used in the

tube, and the date of filling. Something more exact than the commercial name of the glass would be needed in stating the former, but both of these particulars might with propriety be engraved on the tube. LEONARD WALDO

Yale College, New Haven, May 11

"How to Prevent Drowning"

ONE further hint may be added to those of Mr. MacCormac. It is as simple as practical, although it may not have been before recommended in print.

When a person is thrown into the water from an elevation the body sinks for a time, and may not rise quickly to the surface to permit fresh breath to be taken. In that case shut the lips firmly to prevent the escape of the breath, and swallow the breath. This is the art of the diver; it comes naturally to him when he seeks to prolong his stay under water; but it may not as readily occur to one unskilled in diving, whose only desire is to reach the surface. The act of gulping down the breath may be repeated three or four times, and thus protract the chances of escape.

Although every one may tread water, fresh or salt, Mr. Hill is undoubtedly right in saying that all cannot float upon fresh water without assistance from their hands or feet. Not one in ten can do so. When the swimmer shows his toes above the surface his hands are in constant action below, turning half-way round from the wrist and back again, to change the fulciment.

WM. CHAPPELL

Stratford Lodge, Oatlands Park, Weybridge Station

THE bathing—I might almost say the drowning—season is now about to begin, and many lives will unhappily be lost. As the human frame, bulk for bulk, is lighter than water, all that is needful to save life is to permit the body to sink until it shall displace as much water as equals the body's weight. Then paddle gently, as the lower animals do, with hands and feet, the head being held erect, wherever it is desired to go. This direction being carried out is absolutely all that is needful under ordinary conditions to preserve life. These few directions ought to be stuck up in every bathing-place—every boating- and skating-place — in the three kingdoms. Children in every instance ought to be made to tread water from the earliest age, say in shallow slate baths with blood-warm water, or, when convenient and suitable, in some river, pond, or in the open sea. A leather belt with ring, and a stout rod with line and hook, are employed by Portuguese mothers to instruct their children. The mother, rod in hand, stands on the brink; the child learns in the water. In Paris swimming-schools the same procedure is resorted to. The business cannot be begun too soon. I saw mere infants sustaining themselves perfectly in the tepid waters of Africa. Treading water is far safer than swimming in a broken sea. Every adult, man or woman, who has not practised it should begin. Once the conviction instilled that the body is lighter than water, the risk of drowning is reduced to zero. The process involves no uncertainty, no delay. Very different from swimming, it can be acquired at once.

Belfast, May 25 HENRY MACCORMAC

Optical Phenomenon

MR. MURPHY'S experience, described in NATURE, vol. xxiv. p. 80, is general enough. It was observed by Fechner in 1860, and is now commonly associated with his name, though Prof. Brücke of Vienna had also seen and explained the very same phenomenon some years before that. Nor was he the first, for, according to Aubert, there is a still earlier account due to Brewster in *Poggendorff's Annalen* for 1833.

Fechner's side-window experiment, as it is called, is best seen by employing a scrap of white paper on a black ground, or *vice versâ*, the eyes being accommodated for some other distance, so that double images of the paper are secured. Care must also be taken that the light from the window enters the nearer eye only through the sclerotic, so as to receive a reddish tinge. This diffused reddish light renders the eye after a short time comparatively insensitive to red, so that the light reflected from the white paper appears greenish, the black paper alone, from which no light is reflected, appearing of the reddish tinge. In contrast with this, in the other eye, which is sheltered by the nose from the window-light, the white light appears reddish, and the black greenish. Some little time is required for the illuminated eye to be exhausted for red before the contrast is very striking. Such is Brücke's explanation; but who will explain to us this "subjective phenomenon of contrast"? JAMES WARD

Trinity College, Cambridge, May 29

An Optical Illusion

IF your correspondent, Mr. William Wilson, will refer to vol. xxxiii. of the "International Scientific Series," page 86, he will find given by Prof. Le Conte a full description and explanation of the ocular illusion to which he refers in his letter (NATURE, vol. xxiv. p. 53). The explanation is identical with that given by yourself. SAMUEL DREW

Chapeltown, Sheffield, May 24

Occurrence of Neolithic Implements at Acton, W.

IT may interest your readers to know that I discovered, last week, on the surface of a field south of the Priory at Acton, an abundance of Neolithic implements, precisely similar as regards form, type, size, and material to those which occur so abundantly in the neighbourhood of Beer and Sidmouth, in Devonshire. They occur also on a large field on the hill at Acton, west of the Wilesden Railway, and are formed of grey or black chalk flints, which—or the implements—have been imported. On a field south of the Priory I found a flat, circular, grey, quartzite, beach pebble, derived possibly from the Bunter Conglomerate of South Devon, similar to those of the Dorsetshire and Devonshire coasts. Such pebbles are of frequent occurrence on the surface of the fields in the Neolithic districts of Beer and Sidmouth, and have been used as hammer stones and missiles. The association of this pebble with implements so like in every respect to those of South-East Devonshire is very remarkable.

The occurrence of palæolithic implements in the drift of Acton has been known for some years. They occur in remarkable abundance in the high level gravels of this locality as well as in the low level gravels of Hammersmith, and one cannot fail to find in newly-spread gravel examples of the minor implements, such as flakes, drills, &c., and occasionally larger implements. A series of the neolithic implements of Acton I purpose depositing in the Jermyn Street Museum. Their discovery at this locality confirms the conjecture I had formed that neolithic implements might occur in the Thames Valley, from having found implements of neolithic type in the drift, into which they may have got washed. Birds Singing during Thunder

A THUNDER-STORM of great severity passed over us, travelling round from west to south, between 4 and 8 o'clock p.m., May 28, and killing a man in the open air three miles from my residence. The thermometer stood about 70° all the while. During the storm, and even when the thunder-peals were loudest, the chaffinches kept singing, and the blackbirds' notes alternated with the thunder-claps. The rain was moderate, and as the air filled with insects and perfume, the swallows kept busily, skimming even while forked lightning was flashing. Horses in the fields however exhibited symptoms of terror. J. SHAW

Tynron, Dumfriesshire

Fire-Balls

I HAVE read with great interest Prof. Tait's lecture on Thunderstorms, and have had recalled to mind a singular fireball which I had the fortune to see some years ago during a thunderstorm in Portugal. I have a perfect recollection of the phenomenon without referring to my journal of that date.

I was standing in a window on the second floor of the Hôtel Braganza (in Lisbon), which stands close to and high above the Tagus, and had an unbroken view of the river. There occurred a flash followed by an instantaneous crash, but the tail of the flash, however, gave origin to two balls, which descended separately and not far apart, towards the river, and when quite close to, or in contact with the water, burst in rapid sequence, with explosions which might have been the crack of doom.

Sumatra, April HENRY O. FORBES

Sound-Producing Ants

IN NATURE, vol. xxii. p. 583, which has lately reached me, I read a letter from Mr. Peal on sound-producing ants, and I

can corroborate his observations. It is nearly two years since I noted this fact in a species of *Polyrachis*, which makes its papery nests on the under side of bamboo leaves. The noise, resembling very heavily-falling rain, is caused by the insect striking the leaf by a series of spasmodic taps, both with its head and with the extremity of its abdomen, which it *inflexes* while so doing.

I came on a second large brown species in September last in Sumatra. The noise which, as in the case of the *Polyrachis*, resembled heavy rain, could be heard a long distance off. What struck me most about this species was the singular synchronism of the movements. These ants were spread over a space perhaps a couple of yards in diameter on the stem, leaves, and branches of a great tree which had fallen, and not within sight of each other; yet the tapping was set up at the same moment, continued exactly the same space of time, and stopped at the same instant; after the lapse of a few seconds all recommenced at the same instant. The interval was always of about the same duration, though I did not time it; each ant did not, however, beat synchronously with every other in the congeries nearest to me; there were independent tappings, so that a sort of tune was played, each congeries dotting out its own music, yet the beginnings and endings of these musical parties were strictly synchronous.

The Pitt-Rivers Collection: Bell-Clappers—the Tooth-Ornament

IN the account lately given in your columns of the Pitt-Rivers Anthropological Collection I find it stated, in speaking of bells: "The clapper is a late addition to the bell which does not exist in Japan or China." When in West Java a year ago I saw in the possession of a gentleman there a bronze (?) bell dug up on the site of one of the old Hindoo settlements, of which now only the graves remain. It had lost the clapper, but the hook, to which I have no doubt a clapper originally was attached, existed still. The form of the bell was much like those figured by Raffles in his "History of Java."

In speaking also of the development of ornamentation reference is made to the W pattern. In the Lampongs this is the most common and almost the only ornamentation. Its origin may possibly be as Mr. Low suggests; but farther up the country, where adornment is more frequent and varied, I find a very common pattern to be a circle ornamented all round the circumference with this toothed design, evidently, I think, representing the sun, and it is not improbable that on the circle being dropped where it could not well be introduced the "tooth-ornament" alone was retained.

Once travelling near Lake Doon, in the West of Scotland, I entered a lonely hut amid the mountains, where a woman was washing the floor—at least the stones set in it, for they were let into the mud at considerable distances apart. As she finished each stone she ornamented it with a piece of pipeclay with concentric circles, combining, where the stone was larger, two of these concentric ornaments into one by a stalk—as of a stem with two flowers on it . Did she still unwittingly retain the ornamentation of the European Bronze Period?

Sumatra, April

HENRY O. FORBES

ON TOTAL SOLAR ECLIPSES OCCURRING BEFORE THE END OF THE PRESENT CENTURY

AT various times during the last six years we have given in our "Astronomical Column" particulars (including elements) of most of the total eclipses of the sun that will happen before the close of the nineteenth century. As the attention of many astronomers may soon be directed to arrangements for observing the eclipse on May 17th, 1882, we present here, in a collective form, the principal characteristics of such phenomena during the interval in question, which are likely to possess special interest under the circumstances. We shall refer to twelve eclipses, commencing with that of the ensuing year.

(1) 1882, MAY 17.—The most accessible positions on the central line will be in Upper Egypt and the extremity of the peninsula of Sinai about Sherm, but the duration of totality will be greater in the vicinity of Teheran. Where the central eclipse crosses the Nile, totality will commence at about 8h. 33m. a.m. local mean time, continuing 1m. 12s. According to General Stebnitzki's recent determination of the geographical position of the apparatus-room of the Indo-European Telegraph at Teheran, the central line will pass 8″ to the south of it, and here the duration of total eclipse will be 1m. 44s., which may be considered the longest available on this occasion: the sun's altitude will be 67°. The central eclipse passes off the Asiatic coast near Shanghai, running about 18′ north of that place; a direct calculation for Shanghai shows a partial eclipse only, greatest at 5h. 21m. p.m., magnitude 0·996, while at the neighbouring meteorological observatory of Zi-ka-wei, the eclipse is also partial, magnitude 0·994. On the central line in the longitude of Shanghai, the total eclipse continues only 35s. with the sun at an altitude of 18°.

(2) 1883, MAY 6.—In this case we have an eclipse where the totality will extend to nearly six minutes, but unfortunately this long duration falls upon the Pacific Ocean, and it does not appear that there is any land where it can be observed. By the Admiralty chart of the Marquesas, a duration of 2m. 53s. might be available on the Island Fetou-houhou, or Chanel Island, the sun at an altitude of 63°, and totality commencing about 0h. 42m. local mean time. At the head of Anna Maria Bay, Nouka-hiva, there is a partial eclipse only, magnitude 0·97. The central line lies wholly upon the Pacific: greatest duration of total phase 5m. 56s. in about 147° W. and 9° S.

(3) 1885, SEPTEMBER 8.—Observable in New Zealand soon after sunrise. In the longitude of Wellington the duration of totality will be 1m. 55s., with the sun at an altitude of 15°, at Wellington itself the duration will be hardly 40s.; the central line passes some forty-five miles to the north. The greatest eclipse falls in mid-Pacific in 58° S. latitude.

(4) 1886, AUGUST 29.—Totality will continue longer in this eclipse than in any other occurring within the interval which we are considering, but again it will happen that the greatest durations fall on the ocean, in this case upon the Atlantic. At the southern extremity of the Island of Grenada, or in 61° 35′ W. and 11° 59′ S. there will be a total eclipse with the sun at an altitude of nearly 20°, commencing at 7h. 10m. a.m. local mean time and continuing 3m. 15s. In 14° 13′ W. and 2° 58′ S. the sun will be upon the meridian at the middle of the eclipse, and totality will last for 6m. 27s. The central line meets the African coast in about 12° 14′ S. and here the duration of the total phase will be about 4m. 38s., with the sun at an altitude of 39°. [This eclipse is a recurrence of that of 1868, August 18, when the central line passed across Hindostan from near Kolapore to Masulipatam, where the duration of totality was 5m. 45s., but attained a maximum of 6m. 46s. on the west coast of the Gulf of Siam. At its next recurrence, 1904, September 9, the total phase continues 6m. 19s. but in mid-Pacific longitudes a little south of the equator. On September 21, 1922, though there is no land where the totality will be longest, a duration of about 3½ minutes will be available on the east coast of Australia.]

(5) 1887, AUGUST 19.—It was long supposed that the central line in this eclipse would extend to England, but it appears to commence in 11° 39′ E. and 51° 38′ N. It will be most favourably observed in Asiatic Russia, but some fifty miles north of Moscow the total eclipse will continue 2m. 30s. with the sun at an altitude of 17°, and this is perhaps the most westerly station that observers should be induced to fix upon. In Moscow the duration would seem to be about one minute. At Berlin the sun will be totally eclipsed immediately after rising. On Lake Baikal

totality will continue about 3m. 38s., with the sun at an altitude of 50° and near the meridian.

(6) 1889, DECEMBER 22.—The greater duration of totality in this eclipse falls upon the Eastern Atlantic, but where the central line meets the African coast in Angola (about 10° 6′ S.) it continues 3m. 35s., with the sun at an altitude of 56°. At Bridgetown, Barbados, totality commences about 6h. 47m. A.M., with the sun at an elevation of 6°, and continues 1m. 48s.

(7) 1892, APRIL 26.—Almost entirely an ocean track on the South Pacific, commencing indeed in the Antarctic Ocean at a latitude of upwards of 75°: an impracticable eclipse, though the duration of totality attains a maximum of more than four minutes.

(8) 1893, APRIL 16.—Probably, all classes of observation considered, this will be the most favourable eclipse occurring before the end of the century. On the west coast of South America, rather less than a degree north of Coquimbo, where the sun will have attained an altitude of 24°, totality will continue nearly three minutes, commencing about 8h. 14m. a.m.: hence the central line traverses Brazil, passing off the South American continent near Ciara, and here the sun, at an altitude of 77°, and near the meridian, will be totally eclipsed 4m. 44s., or within a second or two of the longest interval possible on this occasion. Perhaps the central eclipse may pass about 10′ north of Ciara. After traversing the Atlantic it enters Africa close to Bathurst, at the mouth of the Gambia, where the total phase still continues about four minutes, thence through Central Africa to a point from 4° to 5° west of Khartoum, where it leaves the earth. From these circumstances an extended course of observations may be expected.

(9) 1894, SEPTEMBER 28.—On this occasion we have either a sea-track or a passage over inaccessible regions, except that the eclipse may ultimately be found to be total in the Seychelles; the tabular position of the moon, upon which our calculations referring to this phenomenon are founded, perhaps admitting of alteration to the amount required. The central line commences in the middle of Africa just north of the equator, leaving that continent near the Juba River, the mouth of which is almost upon the equator. In the longitude of Mahé in the Seychelles it appears to pass about 38′ to the south. The maximum duration of totality occurs in about 86° E. and 34° S., and is close upon two minutes. From this point the course of the central line is in the direction of Macquarie Island, near to which it passes off the earth, without, so far as a preliminary computation enables us to say, certainly encountering land after leaving the African continent.

(10) 1896, AUGUST 9.—Stations will doubtless be found for the observation of this eclipse, as although in the first half of its course, at least, the track lies at considerable northern latitudes, the season of the year is favourable. The central line enters Norway, near Tana in Finmark, and in 28° 46′ E. and 70° 31′ N. the duration of totality is 1m. 43s. with the sun at an altitude of 15°. After rising to a still higher latitude the central eclipse begins to descend, until we find it occurs with the sun on the meridian in about 112° 21′ E. and 65° 38′ N., and the latitude continues to diminish until the total phase leaves the earth. In 136° 21′ E. and 51° 5′ N., near the Amoor River totality continues 2m. 38s. with the sun at an altitude of 46°. The total eclipse may be observed also in the northern parts of Yesso, Japan, but does not afterwards meet land. [This will be a recurrence of the eclipse of 1806, June 16, observed by Bowditch in America, of that of 1842, July 8, well observed in the South of France and in Italy, and of the "Himalaya eclipse" of 1860, July 18, when a numerous party was conveyed to the south-west of Europe in H.M.S. *Himalaya*, there meeting with observers from all parts of the Continent, and unitedly putting upon record important details of the phenomena observed. Its last recurrence was on July 29, 1878, when so good an account of it was given in the United States by American and European astronomers.]

(11) 1898, JANUARY 22.—This eclipse may be well observed in Hindostan, where the central line enters the peninsula in about 73° 25′ E. and 16° 38′ N.; totality will commence at oh. 45m., and continue about 2m. 6s. It commences in Senegambia, and leaves the earth in East Mongolia. Although many observations may probably be made in India, it will be seen that the duration of the total phase is comparatively short.

(12) 1900, MAY 28.—The central line entering upon the earth in the Pacific in 18° N. traverses the south-east portion of the United States, from Louisiana (not far from New Orleans) to Norfolk, on the Atlantic coast, and at the point where it leaves the American continent totality commences about 8h. 47m. a.m., and continues 1m. 40s. with the sun at an altitude of 47°. Crossing the Atlantic, upon which the greatest duration of totality falls, it enters Portugal near Ovan in about 40° 49′ N., and here the total phase continues 1m. 30s., with the sun at an elevation of 42°. The eclipse may be well observed in Portugal and Spain; at Alicante totality lasts 1m. 18s. This eclipse will be a recurrence of that of May, 1882, and the available durations of totality, it will be seen, are about the same on both occasions. In Hallaschka's *Elementa Eclipsium*, by an oversight, this eclipse is represented as broadly annular; the geocentric excess of the moon's semi-diameter over that of the sun will be, however, about 9″.

The following table exhibits the approximate positions of beginning and ending of total phase, and of the central eclipse at apparent noon, for the twelve eclipses included in the above remarks:—

Year.	Central Beginning.	Total at Apparent Noon.	Central Ending.
1882...	3°·1 W. 10°·7 N.	63°·8 E. 38°·8 N.	138°·9 E. 25°·5 N
1883...	155°·9 E. 34°·8 S.	147°·2 W. 9°·2 S.	86°·9 W. 13°·6 S.
1885...	156°·9 E. 40°·9 S.	138°·7 W. 57°·7 S.	75°·6 W. 74°·6 S.
1886...	79°·6 W. 9°·9 N.	14°·2 W. 3°·0 N.	47°·3 E. 22°·0 S.
1887...	11°·7 E. 51°·6 N.	102°·3 E. 53°·8 N.	173°·8 E. 24°·5 N.
1889...	78°·9 W. 15°·4 N.	6°·5 W. 11°·1 S.	60°·9 E. 6°·9 N.
1892...	144°·1 W. 76°·1 S.	138°·7 W. 67°·3 S.	81°·7 W. 38°·4 S.
1893...	95°·7 W. 36°·3 S.	36°·6 W. 1°·0 S.	28°·6 E. 16°·4 N.
1894...	26°·9 E. 1°·7 N.	86°·3 E. 34°·3 S.	163°·0 E. 56°·4 S.
1896...	1°·0 W. 63°·5 N.	112°·4 E. 65°·6 N.	179°·1 W. 18°·6 N
1898...	10°·0 E. 11°·0 N.	68°·8 E. 12°·9 N.	119°·3 E. 45°·9 N.
1900...	116°·6 W. 18°·0 N.	44°·8 W. 45°·0 N.	31°·8 E. 25°·4 N.

A CHAPTER IN THE HISTORY OF THE CONIFERÆ[1]

THE CUPRESSINEÆ

THESE are classed as the first tribe of the Coniferæ in Hooker's "Genera Plantarum," wherein seven genera are recognised. The Cupressineæ are large trees or shrubs, very resinous, with small scale-like leaves. The cones are small and globular, and composed of six, eight, or rarely ten peltate and persistent scales, except in the juniper, in which they coalesce into a fleshy galbulus or berry. The seeds are small, compressed, frequently triangulated, and, except in *Juniperus* and the Biota section of *Thuja*, provided with small membranaceous wings at the angles. The order comprises many of the hardiest shrubs in existence.

Their origin can possibly be traced back to the Permian genus *Ulmannia*, and they seem to have become the preponderating tribe during the Jurassic and Wealden, to judge from the prevalence of wood known as Cupressinoxylon. The earlier forms, described as *Widdringtonites*, *Echinostrobus*, *Thuyites*, and *Thuyopsis*, though of great interest are still imperfectly known, even from the Cretaceous, but with the Tertiary period most of the

[1] Continued from vol. xxiii. p. 414.

existing genera appear, apparently as completely differentiated from each other as at the present day.

A few of the Cupressineæ, as cypress and some of the junipers, inhabit swamps or places liable to inundation, while other species of the same genera seek out the loftiest mountains and excel almost all other shrubs in hardiness, the juniper and cypress being found in Central Asia at altitudes respectively of 15,000 and 16,000 feet.

Many of them seem able to adapt themselves to a great range of climate. *Fitzroya*, a stately cedar 100 feet in height on the western slope of the Patagonian mountains, dwindles to a small bush a few inches high on the confines of perpetual snow, and the Chilian *Libocedrus*, 100 feet high on the Cordilleras, dwarfs to a small bush in Magellan. Of all the genera, however, *Juniperus* is the most hardy, extending itself as low scrub-bushes on most mountain chains to far beyond the limits of trees, and occupying to the south the barren rocks of Cape Horn (*J. uvifera*), and to the north penetrating Labrador, Newfoundland, Hudson's Bay, and Greenland (*J. Canadensis*).

Although of relatively less bulk than the Sequoiæ or the Pines, some species attain colossal dimensions, as the Oregon red cedar, *Thuja gigantea*. This tree, said by Gordon to be from 50 to 150 feet, and by Herschel 200 feet, high, seems actually to have reached an altitude of 325 feet, and a diameter of 22 feet, for a gigantic plank, exhibited by the State of Oregon at the Philadelphia Exhibition, was stated to have been cut at 118 feet from the ground from a trunk of these dimensions. *Libocedrus decurrens* exceeds 200 feet, and in the Himalayas the gloomy *Cupressus torrulosa* has been met with 150 feet in height and 16 feet in girth at five feet from the ground.

The woods of many of the species are valuable—those of *Frenela columnaris*, *Callitris quadrivalvis*, and some species of juniper being esteemed by cabinet-makers for furniture and veneering. The mottled butt wood of the "Thuja" of Pliny, and the "citrus" of Horace commanded fabulous prices during the Roman Empire. Cicero is said to have paid a million sesterces[1] (9000*l.*) for a table made from this wood, and of two tables belonging to King Juba, and sold by auction, one fetched 1,200,000 sesterces, although the largest recorded diameter is only about 4½ feet. The wood is still turned into tazza in Paris, and examples of it are preserved in the Kew Museum. Some of the most valuable gums, balsams, and resins, and amber are obtained from the tribe.

The first, and palæontologically most important, genus is CALLITRIS. This is subdivided into four sections, by many authors recognised as distinct genera—(1) *Pachylepis* or *Widdringtonia;* (2) *Tetraclinis* or *Callitris* proper; (3) *Hexaclinis* or *Frenela;* and (4) *Octoclinis*. The first section is doubtfully recorded as *Widdringtonites*, from the Lias of Switzerland and Würtemberg and from the Wealden and Cretaceous of North Germany, and Kome in Greenland. *Widdringtonia* is definitely found at Aix and other Eocene localities of France by Saporta, in the Miocene of Oeningen, at Bilin, and questionably so in the absence of fruits in the Greenland Eocene. It is now confined to South Africa and Madagascar.

The second section, *Callitris* proper, is distinguished by its cone formed of four truncated valves in pairs, and is represented at present by a single species confined to Northern Africa. Its fruits however are not only met with at Sheppey, but at Aix, St. Zacharie, and Armissan in France, and at Häring in the Tyrol.

Between this and the next section of *Callitris* should be placed, if cupressineous at all, the extinct genus (?) *Solenostrotus* of Endlicher, founded on Bowerbank's figures of fruits with five valves each.

The third section, *Frenela*, has a cone of six scales in opposite pairs, and is now entirely confined to Australia and New Caledonia, nearly two dozen species being more or less known. One of the most distinctly Cupressineous fruits yet met with fossil corresponds exactly with the Port Jackson *C. Endlicheri*, but has eight scales, and therefore falls into the *Octoclinis* section, also Australian, but now limited to a single species.

We have thus the most absolute proof that different sections of CALLITRIS flourished in these latitudes during the Eocene period, and therefore that the Palæarctic, Ethiopian, and Australian botanical regions overlapped and intermingled to some extent at that time. They do not seem, however, to have been present much to the north of our own latitude.

The genus ACTINOSTROBUS does not appear to have been found fossil except by Ettingshausen at Sagor (1859), and even these two specimens seem very indistinct and much smaller than either existing species, and are ignored by Schimper in his list of species. The existing Patagonian FITZROYA has no known fossil representative.

The fourth genus, LIBOCEDRUS, is distinguished by its flattened oblong cone of four to six leathery and very unequal scales, and by its thick scale-like and peculiar foliage. It occasionally forms very large trees, and in distributed over all but the Oriental and Ethiopias regions,[1] though the actual species have a limited range. The range of Libocedrus in the Tertiaries is singular. It appears from below the London clay at Bromley, then completely disappears in Europe until the Miocene, when it reappears at Bilin, Schossnitz, Radaboj, Armissan, Sinigaglia, from near Bonn, from Monod in Switzerland, and the amber-beds of Prussia. Another species, said to be allied to the Chilian tree, is found in the Eocene of Greenland. As most of the species of Libocedrus inhabit considerable altitudes, even reaching the snow level, and all of them are hardy in England, it is fair to infer that prior to the London clay the climate (and this is borne out by the rest of the flora) was much cooler than during subsequent Eocene times. That Libocedrus was really absent from temperate Europe during the latter part of the Eocene period is beyond all doubt, and that we actually experienced a change in climate such as had been inferred from the faunas of the Thanet sands and Woolwich and Reading beds is fully confirmed by the flora.

THUYA has small ovate or oblong cones of 6-10 valvate unequal scales, and foliage somewhat similar to Libocedrus, though less symmetric. There exist twelve to twenty-one species, divided into five sections, and some forming trees that are gigantic. The great majority are Japanese, but two species inhabit the Nearctic regions. The genus first appears in the Arctic Eocenes, descending into Europe during the Miocene, when it formed the vast amber-producing forests along the Baltic. The oldest beds to the south from which it is known, though it is rare there, are those of Armissan in France, and the late Miocenes of Marseilles and Tuscany. It is unknown from England, and the *Chamæcyparites* of the older Eocenes of Europe are now transferred to Sequoia.

The sixth genus, the stately CUPRESSUS, is only known fossil from two German Miocene localities. The existing species are mostly found in mountainous regions.

The seventh genus, JUNIPERUS, is very extensive, and is present in every geographical region except the Australian, being also one of the three British indigenous Gymnosperms. It has been recorded fossil from Aix, Häring, and the amber-beds of Prussia, but the smallness of the fragments and the absence of any traces of berries renders its occurrence, especially in the former localities, somewhat doubtful.

The range of the fossil CUPRESSINEÆ, as ascertained throughout the Tertiaries, is thus seen to be perfectly

[1] Hooker, "Tour in Marocco," p. 389.

[1] As restricted by Wallace.

natural ; the hardy genera are never associated with the more tropical Eocene floras, and the sub-tropical genera did not range farther north than the present temperate latitudes, nor extend into the later Miocenes. Hardy species occupied these latitudes in the old temperate Eocene times, retreated as the temperature increased, and re-descended from the north as it again decreased, reaching finally as far south as North Italy. The habits and even the species of the genera have not materially altered since the Tertiaries commenced, and they appear to furnish comparatively safe data for physiological inquiries. The most remarkable fact taught by them, a fact beyond all question, is that types now distinctive of widely separated botanical regions actually lived side by side together in Western Europe in the Eocene age.

As the true nature of the various Eocene and Miocene floras becomes unfolded, thanks principally to the able work of Saporta, the fluctuations in temperature that Europe and America have experienced will be measurable and their ebb and flow calculable, with some approximation to certainty. The sensational extremes implied by the over-positive determination of fragments that no human being could determine with certainty, will then, it is to be hoped, be once and for ever discredited.

THE STORAGE OF ELECTRIC CURRENTS

PRACTICAL electricians seem to have made up their minds that a system for the distribution of electricity for the purposes of electric lighting or of driving electric motors will be incomplete unless it comprises a means of storage of the currents to provide against the risk of any temporary derangement or inconstancy in the generating apparatus. An accumulator of currents would in fact render the same service in an electrical system as do gasometers in systems for distributing gas, or the hydraulic accumulators in a system of hydraulic machinery.

At the present time much attention is directed to such *accumulators*, or, as they have been hitherto called, *secondary batteries*.

The principle of the secondary battery dates back to the very early days of Voltaic electricity, when in 1801, one year after Volta's "pile" had made its appearance, Gautherot, a French *savant*, observed that wires of platinum or of silver which had served as electrodes for the decomposition of water containing a little salt or sal ammoniac acquired the property of giving a brief current after being detached from the pile. This phenomenon, familiar to every electrician under the name of "polarisation of the electrodes," was observed again by Ritter of Jena, in 1803, with electrodes of gold wire ; and the observation immediately led him to devise a battery from which these secondary currents could be readily obtained, and which constituted the first of all secondary batteries. He tried many different arrangements, using various metals—platinum, silver, iron, &c., but with lead he obtained no result. He attributed this secondary action to a soaking or accumulating of the two opposite kinds of electricity into the surfaces of the plates or into the intervening liquid. The true explanation was given by Volta and Marianini, and later by Becquerel, when they showed that the action arose from the deposits of oxygen and hydrogen, or of acid and of base upon the two electrodes, whose surfaces thus became chemically changed and capable of acting towards one another like the zinc and copper plates of an ordinary battery. Grove, in 1843, brought the matter to a decisive proof by constructing his curious gas battery, in which the positive and negative poles were both platinum plates, the one surrounded by oxygen gas, the other by hydrogen. Ritter's failure to obtain any effect from electrodes of lead arose from his employment of solutions of chlorides as the liquid, the chloride of lead which resulted on the passing of the current being a non-conductor, which at once stopped the current. M. Gaston Planté, who, in 1859, took up the study of the subject, found, after experimenting with many metals, that electrodes of *lead*, when immersed in dilute sulphuric acid, gave rise to very marked polarisation-effects ; for after passing through lead electrodes the current from two Bunsen's cells, the

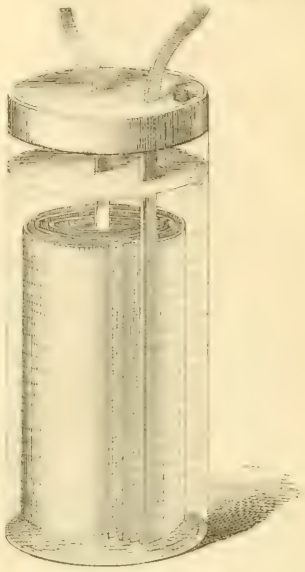

Fig 1.

This figure represents two sheets of *lead*, separated by two sheets of canvas rolled up together and placed in a glass jar containing water, two strips of sheet-lead protruding through the closed top of the jar.

secondary currents were extremely strong and of considerable duration. He therefore constructed large secondary batteries, using for this purpose two sheets of lead immersed in dilute acid. In order to reduce the internal resistance by bringing the opposed surfaces as nearly as possible together the two sheets were of large size and

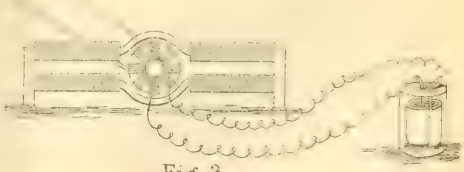

Fig 2

were rolled together in a spiral form, being kept from touching by the interposition of sheets of coarse canvas, or in later forms by means of bands of india-rubber. The general form of a single cell of Planté's secondary battery is shown in Fig. 1. Such cells weighed over twenty pounds, and when properly prepared had an electromotive

force 2½ times that of a Daniell's cell; their internal resistance was also very small, being from one-eighth to one-twentieth of an ohm. These cells improved with use; the liberated gases attacking the surface of the lead electrodes, so that they gradually became of a spongy texture, while the surface of the plate at which oxygen was liberated became covered with a film of brown peroxide of lead. When both electrodes were thus "formed" by charging the cell at intervals of a few days in opposite directions, the Planté cell became a veritable *accumulator*

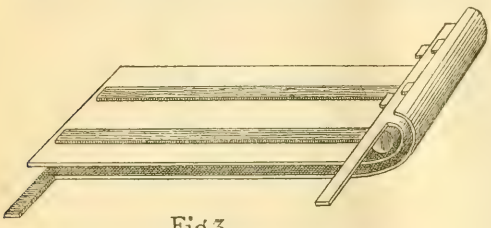

Fig 3

Represents two sheets of lead, separated by strips of thick felt, prepared for rolling together round a roller.

of electric currents, and was able to store up from a comparatively feeble source a supply which could yield vastly stronger effects for a short time. In fact the secondary battery became in Planté's hands a kind of Leyden-jar for storing currents of electricity; the essential point of difference between the two being that while the Leyden-jar accumulates a *charge*, and can be charged or discharged in an instant—or in other words possesses only an "instantaneous capacity"—the secondary battery accumulates currents which may flow into it for many hours, and which may take also a considerable time for their discharge, its "continuous capacity" being very great as compared with its instantaneous capacity. The currents stored up in the secondary battery are however not stored up as accumulations of electricity. They are stored up in the form of chemical work done in the cell, this chemical work being capable of being retransformed at will into the energy of electric currents. When the charging current from an independent battery or from a dynamo-electric machine (see Fig. 2) is passed through a Planté cell, the electrode by which the current enters becomes more highly peroxidised than before, while a corresponding amount of deoxidisation takes place at the electrode by which the current leaves the cell. When the cell thus charged is used as a battery it gives back a current which flows *out* from the electrode by which it formerly flowed *in*; passing through the cell from the deoxidised to the peroxidised electrode, until they are both reduced to a state of chemical similarity. If the cell is joined to the dynamo-machine which charged it, in order to drive it round as an electro-magnetic engine or motor, it will cause it to rotate in the *same* direction as that in which it was driven when used as a generator; the principle of reversibility applying both to the cell and to the machine.

Several forms of secondary battery adapted for storage of currents have been suggested in recent years. In Philadelphia Professors Houston and E. Thomson have tried a modification of the Daniell's cell, in which sulphate of zinc was electrolysed between electrodes of copper, the metallic zinc so deposited afterwards serving as the negative pole of the cell. Another suggestion, due to M. d'Arsonval, was to use an electrode of lead along with one of zinc, dipping into a solution of sulphate of zinc. The charging currents deposited metallic zinc upon the latter and liberated oxygen at the former, which, as in the Planté cell, became coated with spongy peroxide of lead. As this latter is not a very good conductor M. d'Arsonval further proposed to increase the effective surface by laying the sheet of lead horizontal and covering it with leaden shot, which should also become peroxidised.

The latest form of secondary battery is that of M. Camille Faure, described in NATURE, vol. xxiv. p. 68, of which there has been so much talk in the semi-scientific press, and which is now being made the central point of a great financial "operation" in Paris. There can be no doubt that this instrument, though the accounts of its performances have been grossly exaggerated, is an improvement upon that of Planté, of which it is a slight modification. The labour and difficulty of "forming" the Planté cell, that is to say of charging and recharging it until a sufficient film of peroxide of lead should be produced, led M. Faure to try the effect of coating the lead plates at first with a film of *red lead* or minium, a lower oxide than the dark brown peroxide. The two sheets, after having been covered with minium, are rolled together precisely as in the Planté cells, as shown in Fig. 3, a sheet of felt being interposed to prevent internal contact. It was stated by M. Reynier that the capacity of such cells was forty times that of the Planté cell; but four times would have been nearer the mark if cells of equal size were compared. M. Faure's cells are made of large size and weigh 75 kilogrammes, or nearly 200 lbs. It is stated that one such cell would store a sufficient amount of current as to be able afterwards to yield in an hour an amount of work equal to one horse-power. Confirmatory observations are yet needed. Meantime let us just remind the enthusiast who brought over to England the "million foot-pounds" of energy stored up in a Faure cell, that he would have imported a dozen times as much stored energy if he had brought over instead a lump of coal of the same weight.

The uses for such secondary batteries may be of three kinds:—1. They may serve as portable supplies of electricity to be left and called for to recharge when exhausted. 2. They may serve to accumulate supplies of electricity from dynamo-electric machines, and store them until required for furnishing electric light or motive power on a small scale. 3. They may serve as equalisers of electric currents in a system in which the supply is liable to fluctuations. Suppose, for example, a dynamo-electric machine is employed to produce electric light. Any least thing which alters the speed of the machine, even for an instant, makes the light flicker and change in intensity; while the breakage of the engine-strap would at once cause total darkness. But if a secondary battery of suitable dimensions and power were inserted across the circuit between the dynamo-machine and the lamp, the inequalities of the current would be greatly modified. When the light was not in use the battery would store up the current. If the engine failed the battery would at once put forth its power. It is probably in this direction that the secondary battery will find no unimportant field of usefulness.

A SINGULAR CASE OF SHIPWRECK

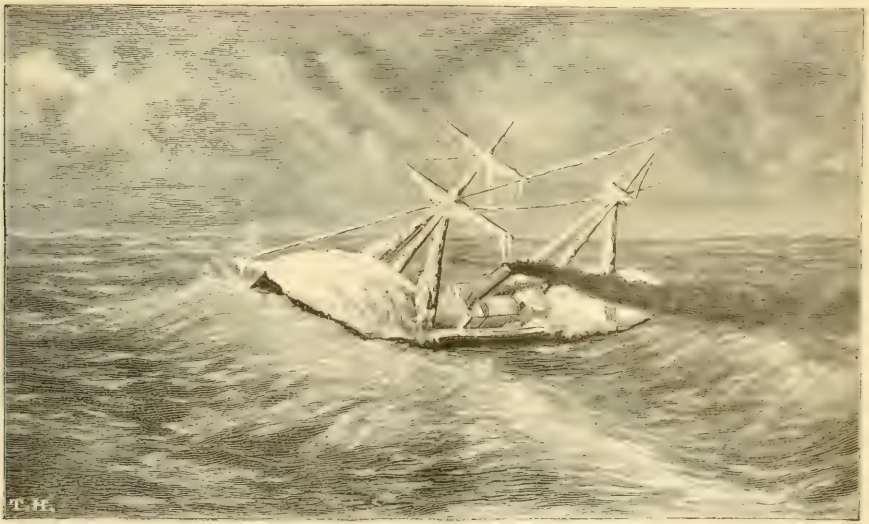
THE wreck of the Danish mail steamer *Phœnix*, which took place off the west coast of Iceland on January 29, was attended by rather unusual circumstances deserving of note. The vessel (about 450 tons burden) sailed with cargo and the mails from Copenhagen for Leith, the Faröe Islands, and Iceland, about the middle of January.

Nothing particular occurred until after leaving the Faröes, when she ran into a severe gale, which rapidly increased to a perfect hurricane, while at the same time the temperature fell to about 50° F. of frost (— 18° F.). Such cold is not extraordinary in these latitudes in winter, but fortunately it is seldom associated with very high winds. Under the circumstances in which the *Phœnix* was placed every sea that she shipped froze, and the deck soon became covered with a foot or two of solid ice.

As time passed on the continued action of the sea raised a perfect iceberg on the forward part of the vessel, while the showers of spray carried along by the steadily increasing gale covered the masts, yards, and rigging with an ever-thickening coating of ice. Two or three days passed without the least abatement of the storm, and then the half-smothered steamer went over on her beam ends. The crew succeeded in cutting away the masts, and she once more righted.

It however was clear, the gale showing no signs of breaking, that the relief was only temporary. The ice continued to form on the vessel, particularly about the forecastle, where, piled high above the bulwarks, and overhanging the sides, it threatened, by altering her trim, to raise the propeller out of the water.

Under these circumstances, on the morning of January 29, Capt. Kihl decided to run the steamer ashore while daylight lasted. At some distance from the land she struck on a sunken rock, and the crew, taking to the boats, only succeeded with the greatest difficulty in reaching the shore, saving nothing but their lives, the English mail, and a bundle of blankets which (when carried ashore) was found to be useless—frozen into a solid lump. Their situation in deep snow on the desolate coast of Iceland, about 100 miles to the north-west of Reykjavik, was very critical, and a party of two or three of the stronger sailors under the command of M. Jaspersin, the first officer, proceeded in search of assistance. It was not however until about three in the morning of the 30th, after suffering great hardships, that the sound of a pony kicking in a shed guided them to a house. The farmers immediately turned out, and eventually the scattered crew, twenty-two or twenty-three in number, were picked up, some of the clever little Icelandic dogs proving themselves most valuable auxiliaries in the search. Many of the men, however, were all but frozen to death in the snow. From this time all possible attention was given to them; but one, having both legs and arms frost-bitten, died; another afterwards had both legs amputated below the knees; and the steward lost three



fingers of each hand. Hardly one escaped more or less injury from the effects of the extreme cold to which they had been so long exposed. Capt. Kihl and the bulk of his crew soon after succeeded in getting to Reykjavik, and on April 13 they sailed in the sister steamer, the *Arcturus*, for Copenhagen. The officers and men of the wrecked vessel are of opinion that had Capt. Kihl not decided on the 29th to run the *Phœnix* ashore in daylight not a soul would have been saved, as the gale did not moderate for several days after; and the steamer, buried as it was under an enormous mass of ice, must have foundered in the night.

In Iceland this storm will be long remembered by the destruction it caused; and it is said that such a terrible winter has not been known for years. Sheep have perished in large numbers, and ponies have been killed to save hay. Then as the Icelanders depend on the outer world for flour, &c., the loss of the *Phœnix* with its cargo was a terrible misfortune. A letter from Reykjavik to a lady in Edinburgh, published on April 21 (and dated the 10th), states that the magazines were empty, and concludes thus: "It was very delightful to see the steamer *Arcturus* coming in the other day after having expected it so long. It brought both news and provisions, so that the poor people in the neighbourhood of Reykjavik can be helped for a while."

J. ALLEN ALLEN

NOTES

CAPT. FREDERICK JOHN OWEN EVANS, C.B., F.R.S., has been made a K.C.B. Among all the crowd of names gazetted for such honours on the Queen's birthday, not one had better deserved it by his services to his country, as well as to science, than the well-known Hydrographer to the Admiralty.

THE Visitation of the Royal Observatory takes place on Saturday. No doubt it will be numerously attended, as it is announced that Sir George Airy has resigned his post for the 1st of August

THIS is a week of *soirées*. The Royal Society *soirée* on Wednesday is followed by the Society of Arts *soirée* to-night, while the President of the Institution of Civil Engineers has issued invitations for another on Friday. These two last are held in the galleries of the South Kensington Museum.

MUCH interest has always been attached by anthropologists to the Stone Age of Egypt, on account of its bearing on the antiquity of man. Hitherto the finds of stone implements have been purely superficial, but in March last General Pitt-Rivers, President of the Anthropological Institute, discovered worked flints two to three metres deep in stratified gravel and mud near Thebes. The gravel had become so indurated in Egyptian times that they were able to cut square-topped tombs supported by square pillars in it, and these have remained in their original condition to this day. Some of the implements were chiselled out of the gravel in the sides of these nombs. General Pitt-Rivers will read a paper giving an account of this discovery at the Anthropological Institute on Tuesday text, the 7th inst.

MR. J. Y. BUCHANAN has, we learn, gone to Italy to see the ship which the Italian Government has fitted out for deep sounding in the Mediterranean.

THE "General Report of the Norwegian North-Atlantic Expedition" is being published in parts, each Memoir being distributed immediately on its leaving the press. The General Report will comprise the following Memoirs:—Capt. Wille, R.N. (Narrative of the Expedition—Description of the Apparatus, how constructed and used—Magnetical Observations); Prof. H. Mohn (Meteorology—Deep-sea Temperatures—Motion of the Sea—Astronomical, Geographical, Geological Observations); Mr. H. Tornoe (Amount of Air in Sea Water—Amount of Carbonic Acid in Sea Water—Amount of Salt in Sea Water); Mr. L. Schmelck (the Salts in Sea Water—Investigation of Bottom Samples); Prof. G. O. Sars (Crustacea, Pycnogonida, Tunicata, Bryozoa, Hydrozoa, Spongozoa, Rhizopoda, Protophyta); Drs. Danielssen and Koren (Holothurida, Echinida, Asterida, Crinoida, Gephyrea, Anthozoa); Mr. H. Friele (Mollusca, Brachiopoda); Dr. G. A. Hansen (Annulata); Mr. R. Collett (Fishes). The publication of the Report, for which a grant of money has been obtained from the Norwegian Storthing, is conducted in conformity with the directions of His Norwegian Majesty's Government. Of the memoirs we have received that on "Fishes," by Mr. R. Collett, and "Chemistry," by Mr. H. Tornoe.

WE greatly regret to learn that Dr. James Croll, F.R.S., has been compelled, in consequence of ill-health, to retire from his position on the Geological Survey. The same reason will account for his not replying to certain correspondence and criticisms which would otherwise have claimed his attention.

DR. AUGUST WILHELM EICHLER, Director of the Royal Botanic Garden and Museum, Berlin, and Professor of Systematic Botany at the University, has recently been elected a Foreign Member of the Linnean Society in the room of the late G. P. Schimper of Strasburg. Prof. Eichler is well known among botanists for his memoir, "Loranthaceæ et Balanophoræ," in Martius's "Flora Brasiliensis"; also as author of "Entwicklungeschichte des Blattes," and "Blüthendiagramme," &c.

WE regret to have to record the sudden death early in March of Mr. John Sanderson, one of the oldest colonists of Natal. From his arrival in 1850 he resided in Durban, where he conducted for many years one of the most influential newspapers. He was otherwise much occupied with public business, and was for some time a member of the Legislative Council. To botanists in Europe he was well known as an ardent explorer of the South African flora and active correspondent, and his name is commemorated by the beautiful genus *Sandersonia*.

A MONUMENT is to be erected to the memory of the late Dr. Broca, the founder of the Paris Anthropological Society; not less than 14,000 francs have already been collected. We are desired to state that the list will soon be closed, and that all subscriptions are to be sent as early as possible to M. Leguay, treasurer of the fund, at the Paris Anthropological Society.

THE Dorpat University offers two prizes of 750 and 500 roubles respectively for the two best models of a monument in memory of Karl Ernst von Baer. Sculptors are informed that the models will be received by the University until September 15 next, and that the carriage to and from Dorpat will be defrayed by the University. Professors Dr. Grosse (Dresden) and Bohnstedt (Gotha) are members of the committee of decision.

A MONUMENT of the celebrated naturalist, Freiherr von Siebold, was unveiled in the park of the Vienna Horticultural Society on April 22 last. The monument is four metres high, and is in the form of an obelisk with a granite pedestal. The upper part is formed by a very ancient memorial stone ornamented with floral designs, which was originally sent to the Vienna Exhibition by the Japanese Government, and was afterwards destined for this monument. Below this stone is a slab of marble bearing an excellent bas-relief of Siebold, the work of Schwanthaler. The whole monument is surrounded by living fir-trees, which were obtained from the Rax Alpe.

THE death is announced of Dr. Ludwig Rabenhorst of Meissen (Saxony). He was a well-known botanist and editor of the *Hedwigia*. Among his numerous publications we may point out "Die Süsswasser Diatomaceen" (Leipzig, E. Kummer) as an indispensable companion to all students of microscopical plants.

THE *conversazione* of the Society of Arts takes place to-night at South Kensington, and that of the Institution of Civil Engineers to-morrow night at the same place.

THE death is announced of Herr Andreas Schmid of Eichstätt (Bavaria), the editor of the *Bienenzeitung*, and author of numerous treatises and pamphlets on bee-culture.

THE Whit-Monday excursion of the Geologists' Association is to be to the Isle of Wight, and will last three days.

DR. SCHLIEMANN has recently been nominated "honorary citizen of Berlin," and has also been presented with the large gold medal "for Arts and Sciences" by the Grand Duke of Mecklenburg-Schwerin.

IN a brickfield near Lützen (Saxony) some 200 sepulchral urns, skulls, and bones have been found. Dr. Virchow has examined one of the skulls, and declares it to be of a very peculiar type, somewhat resembling the well-known Neander Valley skull, but yet differing from it sufficiently to form a special type of its own. The whole discovery at Lützen, combining cremation and ordinary burial, is at present unique. No ornaments of any kind were discovered.

THE Jablonowski Society at Leipzig offers the following prizes in its scientific section for 1881:—700 marks (35*l.*) for an investigation of the motion of Encke's comet, at least for the period since 1848, taking into account all disturbing influences; for 1882: the same amount for a compilation of our present knowledge of the corrosion-figures of crystals, with an account of original experiments on this subject and a deduction of general maxims regarding the cohesion and structure of crystals as well as their molecular conditions; for 1883: the same amount for a determination of the photo-electrical tensions produced in artificial and suitably-coloured crystals by the action of light and their relations to the thermo-electrical effects produced by changes of temperature.

THE works will begin immediately for the construction of the International Exhibition Electrical Railway, as we are glad to state that the request of Messrs. Siemens has been granted by the Municipal Council of Paris.

OUR Paris Correspondent was present last Friday during an experiment made by M. Trouvé on a small boat between Port Royal and Pont des Arts. The boat, measuring 5m. 50 by 1·30, and carrying three persons, obtained a mean velocity of 1m. 30 per second, with a magneto electric motor weighing 2 kilogr., and two series of six Wollaston elements weighing 12 kilogr. each. The trial lasted an hour and a half, and was interrupted by darkness. These experiments will be repeated shortly on the Bois de Boulogne lakes. The motor, which was constructed to give 8 kilogrammetres per second, did a duty which a single rower would have been unable to perform. The electro-magnetic motor was placed on the rudder, and the motion communicated to a small screw placed in the lower part by a chain. This system is not calculated to utilise the whole extent of the motive power generated by the elements, but it dispenses entirely with any alteration to the boat. This last circumstance is considered as decidedly important in popularising the system amongst yachtsmen. There is not the slightest vibration or noise of any description felt on board.

THE lectures which were delivered in connection with the Glasgow Naval and Marine Engineering Exhibition are about to be published.

MR. W. R. BROWNE has issued a carefully revised edition of the Library Catalogue of the Institute of Mechanical Engineers, combining both a list of authors and of subjects. It also contains a Subject-Index of papers in the *Proceedings*, 1847-80.

MR. C. W. HARDING, of King's Lynn, received prizes for two papers at the Recent Norwich Fisheries Exhibition:—1. "Essay on the Artificial Propagation of Anadromous Fish other than the Salmon, and the Re-stocking of the Tidal Waters of our Large Rivers Artificially with Smelts," &c.; 2. "On the Utilisation of Localities in Norfolk and Suffolk suitable for the Cultivation of Mussels and other Shell Fish."

ON Monday night shocks of earthquake were felt at the Observatory on Mount Vesuvius and at the villages at the foot of the mountain, especially at Torre del Greco. At nine o'clock on Tuesday morning the seismographic activity was decreasing.

THE Swiss Federal Commission for Meteorology has been definitively constituted for three years as follows:—M. Schenk, president; Professors R. Wolf (Zürich), Hagenbach (Basel), Plantamour (Geneva), Ch. Dufour (Morges), Forster (Berne), and Weber (Zürich), and M. Coaz Inspector of Forests at Berne. The Commission met at Berne on May 23, and discussed the institution of a Central Board at Zürich. Want of means has prevented it from opening the important meteorological station on the summit of Mount Sentis.

M. DE LESSEPS has been urging upon the Khedive of Egypt the re-establishment of the Cairo Observatory, originally founded by Mehemet Ali; its fine instruments have been long ago dispersed among various establishments. The atmosphere of Egypt is peculiarly favourable for observatory work, and we hope the Khedive will take M. de Lesseps' advice.

A MARINE Exhibition will be held at Hamburg in September next, of which nautical and astronomical instruments will form the principal part.

A CORRESPONDENT (A. H. McC.) of the New York *Weekly Evening Post*, writes on the question of the Sound of the Aurora:—In your edition of Saturday I noticed an abstract from "Record of a Girlhood," in regard to hearing the aurora borealis, and therefore beg to give you my experience on the subject. In the winter of 1846 I crossed the Atlantic from Newfoundland to Greenock in the brig *Amanda*. We had strong southerly winds the whole passage, without seeing the sun until after making land; three days previously a strong southerly gale carried away our only top-sail, leaving us without sufficient after sail, and consequently we were driven far to the northward. The day before we made land the wind suddenly changed to the north-west, and as night approached the sky became clear. At about 9 o'clock p.m. the captain called all passengers on deck, and a more magnificent spectacle was never contemplated—the whole heaven was a blaze of white light, the aurora darted and rushed from every point and reflected each colour of the rainbow. While it lasted we could distinctly hear the sound, as if the folds of heavy silk were shaken, sometimes sharp and quick, and then receding until the sound was lost, according to the intensity of the flash. During most of the time a book could easily be read on deck. The phenomenon lasted about four hours, during which time we all remained on deck. Next morning we made land, which proved to be Barra Head, Southern Hebrides, and were able to lay our course.

ON May 2 the German Fisheries Society held its annual meeting at Berlin, his Imperial Highness the Crown Prince being present. Herr Friedel, the director of the Märkische Museum, delivered a festive address on "Pre-scientific Fishing." Afterwards the president of the Society, Herr von Behr-Schmoldow, read the report for the year, which was highly favourable. Some 6,000,000 ova have been "sown out" in German waters. Excellent results were obtained with 300,000 American salmon ova and a similar number of shad ova. The intercourse with the fisheries societies in Austria, France, and the United States was very successful and remunerative.

AT the annual general meeting of the Sanitary Institute of Great Britain on May 25, Dr. Richardson, F.R.S., who for four years past has acted as Chairman of Council, and who now goes out of office by rotation, after expressing his thanks to his colleagues for all the courtesies they had shown him, said he could not, he thought, conclude his work as chairman more usefully than by giving a short account of some recently conducted researches which he had made as to the periods of incubation of the infectious diseases which the sanitarian has to combat. He proceeded to indicate that there are twenty-six well-known diseases of this kind, and they each have their special periods of incubation, which, though open to exceptions, are fairly regular. The period of incubation was that period which intervened between the acceptation of the poison that caused the disease and the first manifestation of effect. Diseases might thus be grouped according to their stages of incubation into five classes—*Shortest*, *Short*, *Medium*, *Long*, *Longest*. The shortest period was one to four days: under this head came plague, cholera, malignant pustule, and dissection poison. The second period was from two to six days, and under this head came scarlet fever, diphtheria, croup, erysipelas, hooping-cough, influenza, glanders, and pyæmia. The medium period was from four to eight days, and in it are included cow-pox and relapsing fever. The long period had ten to fifteen days, and included in it measles, mumps, typhus, and typhoid. The longest period, forty days, included syphilis, and might include hydrophobia. Dr. Richardson concluded his address by showing the important practical sanitary lessons that were connected with a correct knowledge of these periods of incubation.

THE Technological, Industrial, and Sanitary Museum of New South Wales is, we learn, intended to occupy a similar position and fulfil the same purpose in that colony which the South Kensington Museum, the Bethnal Green Museum, the Museum of Practical Geology, the Patent Office Museum, and the Parkes Museum of Hygiene do in London. To this end, it is intended

to collect together typical collections of all materials of economic value belonging to the animal, vegetable, and mineral kingdoms, from the raw material through the various stages of manufacture, to the final product or finished article ready for use. It is intended that the following shall be more or less completely represented:—Animal products; vegetable products; waste products; foods; economic entomology; economic geological specimens; educational apparatus and appliances; sanitary and hygienic appliances and systems; mining, engineering, and machinery; agricultural tools, appliances, and machinery; also soils, manures, &c.; models, drawings, and descriptions of patents; ethnological specimens; examples of historical furniture and of artistic workmanship in iron and other metals; photographs, electrotype, plaster, and other reproductions of examples of art workmanship where originals are not to be obtained. Exhibition catalogues, trade journals, price lists, and descriptions of new processes or industries. The acting secretary is Mr. Charles R. Buckland.

We have received the abstract of *Transactions* of the Anthropological Society of Washington for the first two years of its existence, ending January, 1881. It contains brief notices of the meetings of the Society, the papers read, as might be expected, relating mostly to American Indians. A paper by Col. Mallory, "On the Comparative Mythology of the Two Indias (Asia and America)" shows that many resemblances exist between them, arising solely, however, from the efforts of two quite distinct primitive peoples to interpret the same natural phenomena. Prof. Gill deals with the Zoological Relations of Man. The principal papers, however, are the annual addresses of the president, Mr. J. W. Powell, on the Evolution of Language, as Exhibited in the Specialisation of the Grammatic Processes, the Differentiation of the Parts of Speech, and the Integration of the Sentence, from a Study of Indian Languages; and on Limitations to the Use of Anthropological Data. Mr. Powell has also a long paper on "Wyandot Government—a Short Study of Tribal Society."

We have received a long letter from Mr. Gerald Massey on our review of his "Book of the Beginnings," which we regret we are unable to print. We should state, however, that the word *bottle*, p. 49, col. 1, line 17 from bottom, was a misprint for *beetle*; and the following extract from Mr. Massey's work (vol. i. p. 145) will show the sense in which he quoted Prof. Max Müller:—"If the first man were called in Sanskrit Adima, and in Hebrew Adam, and if the two were really the same word, then Hebrew and Sanskrit could not be members of two different families of speech, or we should be driven to admit that Adam was borrowed by the Jews from the Hindus, for it is in Sanskrit only that Adima means the first, whereas in Hebrew it has no such meaning."—(Quoted from Max Müller's "Science of Religion," p. 302).

The additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius* ♀) from South Africa, presented by Mrs. Findlay; a Common Marmoset (*Hapale jacchus*), a Black-eared Marmoset (*Hapale penicillata*) from South-East Brazil, presented by Mr. C. Stewart; a Two-spotted Paradoxure (*Nandinia binotata* ♀) from West Africa, presented by Mr. W. H. Hart; a Bennett's Gazelle (*Gazella bennetti*) from Afghanistan, presented by Brigadier-General Tanner; a Globose Curassow (*Crax globicera*) from Central America, presented by Mr. Allan Lambert; a Slow-worm (*Anguis fragilis*), British, presented by Mr. G. Mengee; three Peacock Pheasants (*Polyplectron chinquis* ♂ ♂ ♀) from British Burmah, six Nuthatches (*Sitta cæsia*), British, deposited; two Ring-necked Pheasants (*Phasianus torquatus* ♂ ♀) from China, two Swinhoe's Pheasants (*Euplocamus swinhoii* ♂ ♀) from Formosa, four Chilian Pintails (*Dafila spinicauda*) from Antarctic America, an Antarctic Skua (*Stercorarius antarcticus*) from the Antarctic Seas, a Dominican Gull (*Larus dominicanus*) from the Falkland Islands, a White-marked Duck (*Anas specularis*) from the Straits of Magellan, an African Wild Ass (*Equus tæniopus* ♂) from Abyssinia, purchased; a Cashmere Shawl Goat (*Capra hircus*), a Mouflon (*Ovis musimon* ♀), born in the Gardens; three Variegated Sheldrakes (*Tadorna variegata*) bred in the Gardens.

OUR ASTRONOMICAL COLUMN

A New Variable Star.—Prof. Julius Schmidt publishes an account of his observation of a star of from 8m. to 9m. in Canis Minor on April 1, which had not been remarked as late as March 28, and of which not a trace was visible on the following night. On November 25, 1879, Mr. Baxendell discovered a star in Canis Minor of about 8·8m., and of a decided orange colour, where the *Durchmusterung* showed no star, which gradually diminished, until on January 11, 1880, it was estimated 9·6. Prof. Schmidt gives the position of this star from observations at Athens and at Dunecht, with the places of two of Bessel's stars as follows for 1880·0:—

	R.A.	Decl.	
	h. m. s.	° ′ ″	
W.B., 7h. 1014 ...	7 34 18·04 ...	+ 8 40 20·9 ...	(*b*)
Baxendell's star	7 34 49·98 ...	+ 8 39 30·1 ...	(*x*)
W.B., 7h. 1029 ...	7 34 54·17 ...	+ 8 42 29·4 ...	(*a*)

Examining this neighbourhood with a 5¼-feet refractor on the evening of April 1, he remarked a star (*c*) of between the eighth and ninth magnitude, and by "eine Ordinaten-construction" from a diagram then made, he judged its position for 1880·0 to be in R.A. 7h. 34m. 56·4s., Decl. + 8° 41′·4. If these places are reduced to the epoch of the *Durchmusterung* (1855·0) they will stand as follows:—

	m.	R.A. h. m. s.	Decl. ° ′	
b ...	9 ...	7 32 56·6 ...	+8 43·7	
x ...	9 ...	7 33 28·5 ...	+8 42·8	
a ...	8·3 ...	7 33 32·8 ...	+8 45·8	
c ...	9 ...	7 33 35·0 ...	+8 44·4	without a greater error than 0″·7.

On April 2, at 8h., with the same refractor, not the slightest trace of *c* could be discovered, and on taking the precaution to examine the stars within a space of two minutes (time) preceding and following the place by the previous night's observation, no similar object was found: a star 10m., wanting in Argelander, showed no motion in two hours. On April 3 and 4 Prof. Schmidt was similarly unsuccessful. Baxendell's star had been compared with Bessel's two stars with the Cometen-Sucher on eighty-six evenings between 1879, December 6, and 1881, March 28 (an instance, by the way, of the scrutinising system of observation which the indefatigable astronomer of Athens is accustomed to apply in his variable-star work): on no occasion was any object noted in the place of the star *c*.

Prof. Schmidt has remarks upon this observation to the following effect: if the object had been a distant planet it would have been found on April 2, 3, and 4 close to its place on April 1. If it had belonged to the group of minor planets it would have been readily identified on one of the evenings the vicinity was examined, by means of the *Durchmusterung*, without knowledge as to the direction of motion. If it were a variable star there was a variation of light from 8·5m. to absolute invisibility in twenty-four hours, which has never been remarked in any other variable; and lastly, if it were a *Nova*, of the class to which the well-known stars of 1848, 1860, 1866, and 1876 have been assigned, its illumination is limited to the interval between the evenings of March 28 and April 1, and therefore could have extended only to four days.

Referring the places of the objects observed by Baxendell and Schmidt to the star of 8·3m., No. 1029 of Weisse's Bessel, we find—

	Angle of position.	Distance.
	°	″
For Baxendell's star	207·8	135
For Schmidt's star	153·2	73

Fellöcker's careful work for the Berlin Chart, Hour VII., does not render any assistance in this case. One of our many amateurs might advantageously take up the systematic and frequent obser-

vation of the neighbours of W.B. 7h. 1029. It may be ultimately found that Schmidt's star affords an extreme illustration of the laws affecting variables of the class of U Geminorum.

Can Mr. Baxendell put anything upon record as to dates when he has examined the vicinity, which may bear upon the length of invisibility of Schmidt's star?

THE COMETS OF 1810 AND 1863 (v).—At the suggestion of Prof. Bruhns new elements of the Comet of 1810 have been investigated by Herr Thraen from the ten observations made at Marseilles by Pons, who discovered the comet on August 22. We had previously orbits by Bessel and Triesnecker. The observations are unfortunately affected with considerable errors, but the following appears to be the best system of elements obtainable from them:—

Perihelion passage, 1810, October 6·23793, M.T. at Greenwich.

Longitude of perihelion	63° 46′ 43″	M. Eq.
,, Ascending node ...	308 50 31	1810·0
Inclination	62 55 39	
Log. perihelion distance	9·986603	

Motion—direct.

We subjoin Prof. Weiss's parabolic elements of the Comet 1863 (v), discovered by Respighi at Bologna on December 28; notwithstanding their striking resemblance to those of the comet of 1810, Prof. Weiss was inclined to consider the comets different: he tried an ellipse with period of fifty-three years, but the comparison of the observations in January, 1864, was not so satisfactory as with the parabola. Michez, by direct calculation upon a month's observations, obtained a period of 109 years.

Perihelion passage, 1863, Dec. 27·76369, M.T. at Greenwich.

Longitude of perihelion	60° 24′ 28″	M. Eq.
,, Ascending node ...	304 43 26	1864·0
Inclination	64 28 46	
Log. perihelion distance	9·887344	

Motion—direct.

There is perhaps room for a further and more minute discussion of the observations of 1863-64, though the result may be adverse to the idea at one time entertained that the comets are identical. There was a near approach to the Earth at the end of January, 1864 (0·18), and the perturbations from this cause will require to be taken into account in a more refined determination of the orbit. The comet was observed at Kremsmünster till February 14; Prof. Julius Schmidt sought for it ineffectually at Athens on March 4.

Probably we have, in the case of these comets, an illustration that mere similarity of orbits, even though it may be pretty close, is not to be regarded as proof of identity.

CHEMICAL NOTES

HERR DRECHSEL claims (*Journal Pract. Chem.*) to have converted ammonium carbonate into urea by the continued action of a galvanic current, the direction of which is rapidly reversed by a self-acting commutator.

A MODIFICATION in the process for manufacturing iodine from seaweed is described by MM. Pellieux and Allary (*Bull. Soc. Chim.*), whereby, it is said, nine times more iodine is obtained than by the older process. The unburnt seaweeds are allowed to ferment in large heaps; the liquor which drains off is concentrated and dialysed in Dubrunfaut's apparatus before evaporation. The plants are burnt without further drying.

SEVERAL of the tinned preparations of the St. Louis Canning Company have been examined by Mr. Wigner (*Analyst*). The dietetic value of the corned beef is about twice that of boneless fresh beef; the cooked ox-tongues contain less salt and more nutritive matter than ordinary dried tongues. *Succotash*, an American preparation of haricot beans, Lima beans, and maize, cooked in the tin, with addition of a little fat, is recommended as a good specimen of boiled vegetable food.

THE number 197·2 is generally accepted as the atomic weight of platinum; Herr Seubert has very recently shown, in the *Berichte* of the German Chemical Society, that this number is very probably too high. As the mean of thirty-nine closely-agreeing results, Herr Seubert obtains the number 194·46. If this number is accepted the atomic weight of platinum is less than that of gold.

HERR TH. WILM has studied (*Berliner Berichte*) the action of finely-divided palladium, platinum, and rhodium, when heated in a stream of coal-gas. He finds that these metals decompose the gas, that when palladium is used a deposit of carbon takes place at some distance from the heated metals; that with platinum the carbon is deposited on the metal, but that on heating in a stream of air the carbon is burnt completely away, and the metal remains in its original form; with rhodium, however, the carbon appears to form a compound, the volume of which is considerably greater than that of the metal itself; this compound is decomposed only with difficulty, leaving metallic rhodium in a much more bulky form than that which it possessed before the experiment.

MICHAELIS AND SCHULTE describe, in *Berliner Berichte*, a new derivative of benzene, analogous with azobenzene, but containing arsenic in place of nitrogen. *Arsenobenzene*, $C_6H_5—As=As—C_6H_5$, produced by the action of reducing agents on C_6H_5AsO, forms slightly yellow coloured needles which are insoluble in alcohol and ether, and crystallise well from hot xylene. The new compound, unlike azobenzene, readily takes up two atoms of chlorine, forming—

$$\begin{matrix} C_6H_5—As—As—C_6H_5. \\ \quad\quad | \quad\quad | \\ \quad\quad Cl \quad Cl \end{matrix}$$

DR. A. R. LEEDS describes, in the same journal, the action of nascent oxygen, ozone, and hydrogen peroxide on benzene. Nascent oxygen was produced by the action of moist phosphorus on air in presence of benzene; if the action proceeds in sunlight a large quantity of phenol is produced, together with oxalic acid; but if in diffused daylight no phenol is formed. Phenol was also produced by the direct action of hydrogen peroxide on benzene, but when ozone acted on the same hydrocarbon, carbon dioxide, acetic, formic, and oxalic acids were produced, but no phenol was formed.

IN a preliminary note in the *Berliner Berichte*, Herr Donath states that the ordinary method of volumetric determination of oxidisable substances by titration with potassium permanganate in presence of acid may, in many cases, be advantageously replaced by an inverse process in which a neutral solution of the substance to be oxidised is added to a strongly alkaline solution of permanganate, whereby oxidation occurs with precipitation of manganese dioxide:—thus with manganese salts and with chromic salts the following actions occur:—

(1) $3MnO + Mn_2O_7 = 5MnO_2$.
(2) $Cr_2O_3 + Mn_2O_7 = 2CrO_3 + 2MnO_2$.

A METHOD for determining molybdenum in molybdates is described by Danesi (in *Atti della Accademia*), based upon the fact that hydriodic acid is decomposed by molybdenum trioxide with separation of iodine. A weighed quantity of the molybdate under analysis is mixed with hydrochloric acid and a solution of potassium iodide; the amount of iodine liberated in the reaction is determined by titration with sodium thiosulphate solution. The results are very accurate.

IN the same journal a method for determining nitrites and nitrates in the same solution is described by Piccini: the method is based on the decomposition of ferrous chloride by nitrous and nitric acids with evolution of nitric oxide, and on the greater readiness with which this decomposition is accomplished by nitrous than by nitric acid.

HERR M. GRÖGER has prepared (*Wien. Akad. Ber.*) several sulphochromites, *i.e.* salts of a chromous acid in which oxygen is replaced by sulphur; the following salts are mentioned among others:—

$Na_2Cr_2S_4$	$CdCr_2S_4$
$Ag_2Cr_2S_4$	$SnCr_2S_4$.

THERE are about 300 known optically active carbon compounds. The specific rotatory power of but seven of these has been accurately determined for the pure substance, and for solutions of the substance in various solvents in all possible degrees of dilution; these seven are tartaric acid and ethyl tartrate, cane-sugar, dextrose, terpene from turpentine oil, nicotine, and camphor. The nature and quantity of the solvent employed exerts a marked influence on the rotatory power of the active compound; as a contribution to this subject the measurements made by Herr A. Becker (Deut. Chem. Ges. *Berichte*) of the rotatory power of asparagine and aspartic acid deserve mention. An aqueous solution of either compound exhibits left-handed rotatory powers;

addition of hydrochloric or sulphuric acid diminishes the lævo-rotatory action, and eventually converts it into a marked dextro-rotatory one; addition of acetic acid has a similar, but much less marked effect; with asparagine a point is reached at which the solution, in acetic acid, is optically inactive.

ATTENTION was recently drawn in these "Notes" to an attempt made by Th. Thomsen to show that the numbers expressing the specific rotatory powers of various carbon compounds might be expressed as whole multiples of certain fundamental constants; each of these constants was supposed to be characteristic of a group of allied compounds. Thomsen's methods of calculation have been severely criticised by Landolt (in the *Berichte*), who has shown that from the limited accurate data at our disposal such an attempt as that of Thomsen can only be regarded as a play on numbers, and is devoid of all scientific value.

EXPERIMENTS are described in the May number of the *Journal* of the Chemical Society by Jones and Taylor, which appear to leave little doubt that these chemists have succeeded in preparing a gaseous hydride of boron, and that the probable formula of this compound is BH_3. The new compound—the existence of which establishes another point of analogy between boron and the nitrogen elements—is prepared by decomposing magnesium boride by a dilute acid; the gas has only been obtained largely mixed with hydrogen; it burns with a green flame, and is decomposed by heat with deposition of boron.

IN the course of a paper on the appearance of nitrous acid during the evaporation of water (Chem. Soc. *Journal*), by Warrington, experiments on the detection of this acid, by the use of hydrochloric acid and naphthylamine hydrochloride, are described, which show that one part of nitrous acid is easily detected in 10,000,000 parts of water, and that as small a quantity as one part in 1,000,000,000 can be detected.

IN the *Zeitschrift für anal. Chem.* Herr Seelheim describes experiments on the percolation of waters through soils, from which he draws the following general conclusions:—Only that stratum of any soil which is composed of the smallest particles need be considered in determining the permeability by water of the soil of a district. The composition of a soil must be ascertained, otherwise experiments on a large scale furnish no measure of the permeability of that soil. The thickest stratum of sand allows the passage of many hundred times more water than a layer of clay only one centimetre thick. The permeability of dykes may be regulated by inserting layers of clay between layers of sand.

SMALL quantities of carbon monoxide may be detected, *e.g.* in the air of rooms, by drawing the suspected gas over powdered glass moistened with diluted blood, shaking the blood with a drop of ammonium sulphide and examining by the spectroscope. Strips of paper soaked in a solution of 0·2 gram. palladium chloride in 100 c.c. water serve to detect carbon monoxide: the dried slips are suspended by platinum wires in a large flask with a very little water, and the flask is corked; with five parts of carbon monoxide in the atmosphere of the flask, a black shining deposit of metallic palladium appears on the paper in a few minutes; with one part, in two to four hours; and with 0·5 part, in from twelve to twenty-four hours.

A USEFUL historical account of the investigations made on the subject of dephosphorising pig-iron, appears in *Dingler's polytechnisches Journal*, and in abstract in the May number of the *Journal* of the Chemical Society.

THE rate of chemical reactions having been lately the subject of several investigations and discussions, M. Kayander publishes in the Russian *Journal* of the Chemical and Physical Society (vol. xiii. fasciculé 4), the results of his last measurements. Without seeking to establish theories as to a connection between chemical affinity and the rate of reactions, M. Kayander simply tries to make measurements in a branch of chemistry insufficiently worked until now. To simplify the results he has employed a solid body and a liquid one, and has measured the rate of dissolution of magnesium in various acids; the magnesium was taken in the shape of small plates, having a surface of about 2000 square millimetres; the acids, in solutions of 0·01 of the atomic weight (in grammes) in a litre of water. Experiments as to the influence of various degrees of concentration will be published in a second paper. As to the influence of time, he arrives at the conclusion that the reaction begins at the very moment of the immersion of the magnesium in the acid; acids when mixed produce the same action as if taken separately. As to temperature, its influence is precisely that which it exercises on the diminution of the internal friction of the particles of the liquid against one another, and does not seem to influence the chemical properties of the reacting bodies; the figures M. Kayander has arrived at from a long series of measurements establish that the speed of the reaction is inversely proportional to the internal friction of the medium. The researches will be continued.

PHYSICAL NOTES

ON heating a plate of boracite lately Herr Klein (*Gött. Soc. of Sci.*) was surprised to observe a complete change of the optical image. The boundary lines of the optical fields prove variable with temperature, and often wholly disappear, perhaps reappearing in quite different places. Herr Klein concludes from these and previous observations that boracite does not owe its origin to a twin-like formation of parts of lower symmetry, but is regular, and produces simple individuals; and the optical properties, apparently in sharp contradiction to this, are really due to tensions produced in growth. These divide the crystal into parts of different tension, of which the sometimes stronger suppress the weaker, for certain temperatures and positions of the crystal. (Similar properties in crystals of analcime have been described by Herr Ben Saude to the Göttingen Society.)

AN ingenious, somewhat complex, apparatus, named an *automatic methanometer*, or automatic analyser of fire damp, has been recently brought before the Geneva Physical Society by Prof. Monnier (*Arch. des Sci.*, April 15). The fire-damp, in presence of air in excess, is decomposed in a glass vessel by a platinum wire rendered incandescent, and the condensation produced acts directly on a mercury manometer, having platinum wires inserted in its tube. The air of the mine is automatically forced by bellows, every hour and half hour, into the burner. The receiving apparatus stands in the central office. The system includes several electro-magnets, two batteries, pendulums with escapement, an alarm-bell, &c.

THE influence of pressure on the electric conductivity of metal wires has been studied anew by M. Chwolson (Imp. Acad. of St. Petersburg *Bull.*, March); Wartmann's previous experiments, in which wires were compressed between steel plates with caoutchouc lining, having failed to show whether pressure changes the *specific* resistance. M. Chwolson used a piezometer, giving pressures up to 60 atmospheres, the wire being wound round a glass tube, then passed through it, and the tube inserted in another, which was connected with the piezometer. (The two wire ends were brought out through binding screws.) Among other results, at 3·8 C. the copper wire showed a relative diminution of resistance of about 0·0000013 by one atmosphere of pressure; a hard brass wire about 0·0000011; and a lead wire (at 7° C.) about 0·000011, or ten times more than the brass. Pressing at 17° C. the calorific action preponderates over the direct action of pressure for copper and brass, while the reverse occurs with lead. Moreover, the author proves, in the case of the brass wire, that the pressure causes change of the specific resistance besides change of the resistance through change of the length and thickness. Every relative change of volume involves a relative change of the specific resistance about 3·6 times as great.

M. MASCART showed recently how the phenomenon of Talbot's fringes could be applied to measuring the refractive indices of gases and the difference between the refractive index of a solid and that of a liquid. M. Hurion has further thus measured the difference of the refractive indices of liquids, and in the *Journal de Physique* for April he shows how the refractive index of a liquid may with those fringes be directly determined. The two interferent rays are rendered vertical, so as each to traverse one of the halves of a partitioned rectangular vessel with glass bottom. The liquid being first at the same level in both divisions, its level in one is gradually lowered by a special contrivance, and this has the effect of displacing the fringes in the field of the tele cope. Let e be the variation of level, f the number of fringes that have passed a point in the field corresponding to light of wave-length λ, then $e(m-1) = f\lambda$. The letter m represents the refractive index of the liquid for light of wave-length λ. (For further details we refer to M. Hurion's note.)

PROF. TROWBRIDGE lately observed that a steel bar magnetised to saturation at 20° C. and subjected to a temperature of −60° C. lost 66 per cent. of its magnetism (a much greater percentage than that formerly observed by Wiedemann).

PROF. ROBINSON of Ohio concludes from experiments (*Jour. Frankl. Inst.*, March) that vibrations in extended media from a remote single centre of disturbance, can only be longitudinal, even in light; that vibrations will be to some extent transversal when due to two or more centres of disturbance not in the same line; and that undulations, to be in a condition called polarised, must consist of vibrations which are transversal, and that no necessity exists for assuming vibrations transversal in front of a polariser. These views are not only contrary to the accepted wave-theory of light, and to the conclusions derived from Maxwell's electromagnetic theory, but appear to be directly negatived by the experiments of Stokes and Figeau.

IN his third paper on electrical shadows (*Gott. Soc. Nachr.*, February 5) Herr Holtz studies, *inter alia*, the differences in form of the light surface and shadows from the two electricities; the effects of using differently-conducting surfaces under the silk, and of using convex and concave spherical or cylindrical surfaces; the double shadows from two surfaces used as electrodes; the use of a silk screen between pointed electrodes, &c.

A NEW seismometer is described by Dr. G. Wagener of Kioto, Japan, for which he claims several advantages over the ordinary heavy-pendulum seismometers. It consists of a strong rigid frame in the form of a short quadrangular pyramid, from which is suspended an iron ball weighing about fifty pounds by means of a bundle of untwisted silk fibres three feet long. Below this ball is an indicating pendulum consisting of a hollow sphere pivoted near its centre of suspension upon a small polished ball, also rigidly fixed to the frame, and carrying beneath it a light arm, whereby its motions are multiplied twenty-four times. A small sphere fixed to the bottom of the iron ball plays into a cavity in the summit of the indicating pendulum. The latter has, by reason of its construction, a *very* short period of oscillation as compared with that of the iron ball. Hence when an earthquake occurs the inertia of the heavy ball will keep it for a considerable time in its position, while the pointer of the indicating pendulum moves toward the region whence the disturbance came, and can return almost instantly if the horizontal displacement be succeeded by a displacement in the opposite direction. That the movement of the pendulum may be registered accurately in point of time, a small silk thread attached to the bottom of the indicating pendulum passes through a small eye-hole in a porcelain plate immediately beneath, and thence passes round a light indicating wheel which is also in connection with a lever which at the slightest movement drops, and stops a clock. A kindred apparatus is employed to register the direction of the shock, eight threads from the indicating pendulum of a similar instrument being wound round eight indicating wheels for the eight chief points of the compass. For these instruments it is claimed that there is less error from oscillations than in the usual instruments, the inertia of the indicating pendulum checking the tendency of the weight to swing. A further registering apparatus, consisting of a chronograph drum actuated by a clock which is started by the first shock, is also described. It does not appear that the registering apparatus of Dr. Wagener is in any way an improvement upon the electrical apparatus hitherto employed. Lastly, Dr. Wagener describes an instrument for measuring any possible vertical displacements, a heavy body of considerable inertia being counterpoised while immersed in a tub of water, its movements being magnified by a lever and registered by a thread-wheel arrangement.

M. GAIFFE gives us reason to suppose that part of the disturbance in telephone lines, usually set down to "induction," is due to the conducting-wires being of a magnetisable metal iron, which, when moved in the magnetic field of the earth, experience induction-currents. M. Gaiffe introduced into a telephone-circuit two pieces of steel wire, one magnetised, the other not. On hitting them so as to make them vibrate sharply, sounds were produced in the telephone more strongly by the magnetised strip. The remedy is obviously to employ conducting-wires of some non-magnetic substance, such as copper or manganese bronze.

ACCORDING to P. Tacchini, there are in the sun two regions of spots and faculæ at about equal distance (20° and 22°) from the equator, and about the same longitude, which showed continual activity last year. The fact he considers important for theories as to the sun's physical constitution.

THE last number of the *Journal* of the Chemical and Physical Society of St. Petersburg (vol. xiii., fascicule 4) contains two letters by Prof. A. M. Boutleroff on ice under critical pressure. The former of them was written on February 13, when Prof. Boutleroff had not yet received the number of NATURE which contains a detailed description of Prof. Carnelley's experiments; the second on March 17. The experiments which he has made, and which he describes in this second letter, were made, Prof Boutleroff says, on the same conditions as those of Prof. Carnelley, but the temperature of ice remained at −6°; a rise of temperature was observed only when a part of the bulb of the thermometer was free from ice, but even in this case it was very slow. "The refrigerating influence of ice was quite manifest, but it was not at any time possible to discover anything showing a rise of temperature." Prof. Boutleroff supposes that Prof. Carnelley has raised the temperature of his thermometer without raising that of ice. "It is true," he says, "that the calorimetric experiment of Prof. Carnelley seems to speak in favour of a heating of the ice itself; but can we not suppose that a kind of covering of hot vapour which was around the ice, remaining on its surface, was transported into the water of the calorimeter, and there neutralised the refrigerating power of the ice?" Prof. Boutleroff proposes also, for the same experiments, to make use of a cryophorus which might be easily appropriated for that use, and which he describes in that case as a cryoscope. When repeating Prof. Carnelley's experiments with a cryoscope, Prof. Boutleroff happened to raise the temperature of the thermometer to +40°, whilst the bulb of the thermometer was *nearly* completely covered with ice; but he failed to raise the temperature when he covered the surface of the bulb with a small sheet of platina. He concludes that the bulb of the thermometer in those cases, when it shows a temperature above zero, enters into contact with ice only at some few spots; and the rise of the thermometer might be explained, not only by the thermal translucency of the ice, but also by the circumstance that the vapour disengaged by the melting ice is heated, and reaches the bulb of the thermometer by the small channels formed in the ice; he therefore concludes that Prof. Carnelley's condition as to the ice being in a special state not quite reliable.

GEOGRAPHICAL NOTES

DR. WILD, president of the International Polar Commission, has issued a circular stating that six countries have already intimated their intention to co-operate in carrying out the scheme of simultaneous meteorological, magnetical, and other physical observations in the Arctic regions. These countries, with the proposed stations, are Denmark at Upernivik, Norway in Finmark, Austria-Hungary in Jan Mayen, or perhaps East Greenland, Russia in Novaya Zemlya and at the mouth of the Lena, Sweden in Spitzbergen, and the United States at Point Barrow and in Lady Franklin Bay. Should other countries send in their adhesion to the scheme, this disposition of the stations may be somewhat modified. We are glad to see there is a probability that Germany may establish a station in the Island of South Georgia, and France a station at Cape Horn. An interesting feature in the scheme is that two of the eight proposed Arctic stations are to be equipped at the expense of private individuals, viz., the station in Jan Mayen or in East Greenland at the expense of Count H. von Wilczek of Vienna, and the station in Spitzbergen, as our readers are already aware, by M. L. O. Smith of Stockholm. Is it possible that no public-spirited Englishman will be found to provide the means for England co-operating in this truly international scheme of physical observations in the Polar regions, which play such an important *rôle* in the meteorology of the globe?

As much has been heard of late respecting the magnificent harbour which the French are likely to make of Lake Bizerta in Tunis, it may be well to correct a misapprehension which has long existed as to its depth. Even in the most recent gazetteers this is said to be fifty fathoms, whereas in a brief but excellent paper which he sent to the Geographical Society many years ago, Admiral Spratt, speaking from his own soundings on the spot, explicitly states that the greatest depth of water in the lake is *eight* fathoms, with an average of from five to six fathoms. This would no doubt be sufficient for all practical purposes, but at the

same time it is vastly different from the great depth given to the lake by old travellers, whose mistake has been perpetuated.

In his anniversary address to the Geographical Society last week Lord Aberdare paid a just tribute to the services rendered to geography in the region west of Lake Nyassa by Mr. F. C. Selous, who has hitherto been best known as a mighty hunter of large game. This gentleman, we learn, in 1878 penetrated for 150 miles the unknown country north of the Zambesi, in the direction of Lake Bangweolo. He has since crossed in various directions the Matabele country south of the Zambesi, discovering two new rivers and defining the courses of others which had previously been laid down from vague information. His notes on the River Chobe have already been published by the Geographical Society. We understand that the fine trophies of the chase which Mr. Selous brought back from South Central Africa have been placed in the hands of Messrs. Rowland Ward and Co. for preparation.

From the report of the progress of the Ordnance Survey which has just been issued, accompanied by useful diagrams, we learn that it is expected that the whole survey will be completed by 1890, as the staff is to be augmented in consequence of increased funds being placed at the disposal of the Director-General.

The programme of the first German "Geographentag" at Berlin, on June 7 and 8, contains the following addresses:—Prof. Zöppritz (Königsberg), on the condition of the earth's interior; Prof. Neumayer (Hamburg), on the importance of magnetic researches from a geographical point of view; Prof. Rein (Marburg), on the Bermuda Islands and their coral reefs; Prof. Bastian (Berlin), on the problems of ethnology; Prof. Kirchhoff (Halle), on the methods of teaching geography in schools. Professors Wagner, Meitzen, and Ascherson will speak on similar subjects.

Dr. Crevaux has completed his third South American journey. He descended the Guayabero River (a tributary of the Orinocco) on rafts, and made an exact survey of this river. The survey comprises 1275 miles, of which 375 are a complete desert. By the assistance of natives Dr. Crevaux and his companions reached Ciudad-Bolivar, whence they embarked for Trinidad on board a steamer. Shortly before the end of the journey one of the travellers, a sailor of the name of Burban, was killed by a sting-ray (*Trygon pastinaca*). Later on Dr. Crevaux visited the villages of natives in the Orinocco delta, collecting interesting anthropological data.

The Central Union for Commercial Geography at Berlin intends to erect a Commercial Geographical Museum in that city. The preliminaries are so far completed that a hall for exhibiting the objects has been hired, a provisional committee formed, and the bye-laws printed. The Union is rapidly extending its branches all over Germany. Among the latest foundations are those at Cassel, Marburg, Hanau, Frankfurt, and Wiesbaden, *i.e.* no less than five in the province of Hessen-Nassau.

At the May meeting of the Berlin Geographical Society the latest news of the German explorers in Africa were communicated to the members. A letter from Dr. Rohlfs was dated from Gondar. The traveller knew nothing of the death of the King of Abyssinia. The disposition of the king for the further journey of Dr. Stecker was very favourable, and the latter was to leave at once for Shoa-land with a guide. Dr. Pogge and Lieut. Wissmann had arrived at Malange on January 25. Here they intended to stay a while before leaving for the interior. Dr. Buchner arrived at Malange on March 8 on his return journey, and met Major von Mecho. Buchner's misfortune of being obliged to turn back after three unsuccessful attempts to penetrate further is already known to our readers. From Madagascar a letter was received from Dr. Hildebrandt. He left Tananarivo on February 17, and travelled southwards with great hopes of a speedy success.

A letter from Dr. Junker to the Austrian Consul at Chartum dispels all the rumours afloat regarding his supposed assassination. He only returned to his station in December last from the journey he had taken. He first crossed the Welle River and travelled in a westerly direction to the Mangbattu tribe. Then he proceeded to some Government stations in Eastern Mangbattu land, getting a little beyond Munsa's former residence, in the vicinity of which is Miam's tomb (not in the Niam Niam land, as indicated by the Italian map). The traveller crossed the Gadde and Bibali rivers at their confluence, and then returned to his station.

The new number of *Le Globe* opens with a continuation of M. de Morsier's papers on the plains and deserts of the two continents, and also contains a sketch of the geographical work of last year by M. Bouthillier de Beaumont, as well as notices of the Arctic campaign of 1880 and the *Jeannette* expedition.

Some long letters have recently been received from Père Livinhac, the head of the Algerian Missionary Expedition in Uganda. In referring to the organisation of the country he says that under the *Kabaka*, or absolute monarch, are the chiefs of the great families, called *Mohamis*, of whom three specimens came to England last year with Messrs. Wilson and Felkin. After these come chiefs of inferior rank, who own allegiance to the *Kabaka* through the *Mohamis*. Last of all is the class of slaves or *Wadu*. Mtesa, Père Livinhac says, is regarded by his subjects as a species of divinity, and they attach a supernatural virtue to objects which he has touched. He however appears to be very much under the influence of a clique of *Mohamis*, who threaten to dethrone him if he encourages foreigners.

The Queensland Government have lately issued a large scale map of part of the Colony, on which is laid down the proposed route of the transcontinental railway to Point Parker, on the Gulf of Carpentaria. This, we observe, crosses the lower course of the Gregory, where, according to a recent official report, that river overflows and covers most of the plains for a considerable distance on either bank. It is difficult to reconcile this uncomfortable fact with the report of Mr. Watson's expedition, to which we lately referred, that high ground ran right down to Point Parker. If this be really the case, the surveying expedition must have followed a different course to the westward of that laid down for it, possibly crossing the Gregory at a much higher point in a comparatively unknown part of the country.

We regret to learn that Père Law, whose unfortunate expedition from Gubuluwayo to Umzila's country was referred to in Nature of May 5, died of fever and general exhaustion at that chief's kraal last November. During his comparatively short stay in Africa he had rendered conspicuous service to geography by the determination of numerous heights and positions.

A very interesting experiment is to be tried in West Central Africa by the members of the Living-tone (Congo) Inland Mission. We understand that seeds of the different species of Chinchona, which have been obtained from the Government plantations in India, are to be sent out to them with a view to ascertaining whether it could be successfully cultivated in the mountain valleys of the Congo.

It is probable that the successor of Admiral La Roncière le Noury, late President of the French Geographical Society, will be M. Ferdinand de Lesseps.

SOLAR PHYSICS—SUN-SPOTS [1]

To the student of science who contemplates the sun by day or the stars by night two questions will inevitably occur. The first will have reference to the source from which those vast orbs have derived their stupendous store of high-class energy; the second to the astonishing regularity with which they are able to give it out. It is not impossible to measure in a rough way the amount of heat which our own sun must have possessed. For in the first place we are forced to allow that our luminary must have shone as it does now for millions of years. In the next place the amount of solar heat received by the earth in one year will about liquefy a layer of ice 100 feet thick covering the whole surface of the earth; and lastly, the sun gives out 2,300,000,000 times as much heat as the earth receives.

These considerations viewed together will perhaps enable us to form a faint conception of the amount of light and heat which our luminary must have given out during its prolonged existence. And yet the sun is by no means one of the most powerful stars, being only about the average in brightness.

We ask then, in the first place, from what source has this inconceivably vast store of energy been derived? If science be not able with absolute certainty to reply to this question, it is yet able to indicate the most probable origin of the supply.

The only hypothesis yet thought of that can account for it is that which first occurred to Mayer and Waterston, and which has been worked out by Helmholtz and Thomson in such a way

[1] Lecture in the Course on Solar Physics at South Kensington: delivered by Prof. Balfour Stewart, F.R.S., April 27.

as almost to prove that there is no other known power capable of producing such a stupendous result.

According to this hypothesis we may imagine the particles of matter, when originally produced, to have been at a great distance from each other, all however being endowed with the power of gravitation—forming in fact a chaotic mass. As these particles gradually came together in virtue of their mutual attraction, heat would be generated in the condensing mass, and it has been calculated that this cause, by storing up a vast amount of heat in the sun, is sufficient to account for its wonderful outpouring of heat and light throughout a long series of ages.

But the whole of the riddle is not thus solved. A man may have vast resources and yet a total absence of ready money. Or a nation may have plenty of food and yet not be able to bring it fast enough into a famine-stricken district. And so the sun may possess in its interior abundance of high-class energy and yet be unable to bring it quickly to the surface—indeed it has been calculated by Sir William Thomson that if the sun were an incandescent solid body its surface would probably cool in a few minutes of time. The perplexing fact about the sun and stars is not so much that they have somehow obtained a vast store of energy, as that they are able to bring it to the surface with an astonishing regularity. Nevertheless this regularity, great as it is, is not apparently perfect. There are a good many examples of variable stars of which some few suffer sudden and extreme changes of brilliancy, while in others the variation is much less conspicuous. In these orbs the transport service by which the heat is brought to the surface appears to work unequally, and even in some cases to break down altogether. Were we much nearer to them than we are we might study these inequalities with advantage, and perhaps gain some insight thereby into the nature of the wonderful machinery that brings the heat to the surface.

As it is however we must chiefly confine ourselves to a study of the sun. Can we therefore hope to find out the nature of the machinery by which the light and heat of our sun are brought to the surface? and is this machinery unequal in its action? Is the sun, in fine, a variable star? First of all, let us have a clear conception of the precise meaning of this question. No doubt the clouds by day and the earth itself by night interpose themselves between us and our luminary so as to render its direct influence exceedingly variable; but this is not the point. Frequently in passing along the streets of an evening we see into the interior of some room which has just been lighted up; but immediately the blind is pulled down, and we see it no longer. The gas may however be all the while burning behind the blind with a constant lustre; or it may be that from water in the pipe or some other cause the flame is intermittent. Now this is the point which we wish to determine about our sun. Is sunlight intrinsically constant, or is it subject to variations? and if so, can we determine the extent and the periods of these variations? Now at first sight it seems exceedingly strange that we are compelled to ask this question.

It might naturally be imagined that astronomers, who can give us the light variations of Beta Lyræ or some other variable star with the greatest precision, must certainly be able to give us similar information about the sun. That they are totally unable to do so is unquestionably very strange. When however we begin to examine we find several reasons for this curious failure. In the first place we must all be glad to think that within historic times at least the variations of the sun's light-giving power can never have amounted to a large proportion of the whole. Had this been otherwise none of us could have been alive at this moment to speculate on solar variability.

Nevertheless these suspected differences, although not exceedingly great, may still be large enough to enable astronomers in some remote part of the universe to pronounce our sun to be a variable star. How is it then that we who are mainly concerned in this variability are yet unable at first sight to decide upon the fundamental question of its existence?

We have not far to seek for an answer to this enigma. The fact is we are too near and too deeply concerned in the issues to be able easily to detect the variation. We have never the opportunity of comparing the sun's light with the pure light of the stars in the way in which we can compare the light of one star with that of another. We must therefore resort to means by which the direct light and heat of the sun may be accurately measured. Now it cannot be said that instruments for this purpose do not exist, but they have not been systematically made use of to determine this important point, and indeed there almost appears to be a reluctance in humanity to face the fact of the sun's variability.

When, in process of time, the telescope came to be invented, by its means Fabricius and Galileo speedily discovered that the face of our luminary was not altogether free from spots. This fact had been previously known to the Chinese, who in the course of their long and peculiar civilisation had recorded many instances where such spots were large enough to be visible to the naked eye. But at present we have to do with the progress of European thought. The first accurate observer of these phenomena was Hofrath Schwabe of Dessau, a distinguished German astronomer. More than fifty years ago he set himself to the task of taking frequent sketches of the disk of the sun, which might record approximately the positions and areas of the various groups of spots. For forty years he continued to labour at this somewhat monotonous task with great perseverance, until at length his unwearied labours were crowned by a singular and unlooked-for discovery. This consisted in the evident periodicity of these phenomena. Daring some years Schwabe found the sun to be almost entirely free from spots, while on other occasions the solar disk was mottled over with very frequent groups, the period from maximum to maximum, or from minimum to minimum, being nearly eleven years. From the observations of Schwabe and others it would appear that 1828, 1837, 1848, 1860, and 1870 were years of maximum-spot frequency, while 1833, 1843, 1856, 1867, and 1877 were characterised by a nearly total absence of spots. Carrington, of this country, followed in the steps of Schwabe, and gave the world a very accurate record of the spots which appeared from 1854 to 1860 inclusive.

In 1858 De La Rue introduced the application of photography to solar research, and since then photoheliographs have been at work at Kew, Ely, and Greenwich, in this country, at Wilna and Moscow in Russia, at Mauritius, Melbourne, India, and Cambridge, U.S., more or less continuously up to the present time.

I can only allude to the magnificent solar pictures produced by Langley at the Alleghany Observatory, and more recently by M. Janssen, the distinguished French astronomer, as forming a new point of departure in the history of solar delineation. Janssen's pictures are more than a foot in diameter, and in them every minute detail of the sun's structure is accurately represented.

But it is time to tell you what a sun-spot really is. Prof. Wilson of Glasgow made in 1774 an observation which greatly startled the scientific world. He found that sun-spots behaved exactly as if they were caverns with sloping sides dug into the body of the sun. The bottom of these caverns is generally black, while the sloping sides are less so. The black portion is therefore called the *umbra*, while the less black sloping sides are called the *penumbra* of the spot. It is easy to explain the nature of Wilson's reasoning. The sun, it is well known, revolves on its axis about once in twenty-six days from east to west, so that a spot will take about thirteen days to travel across the visible disk or hemisphere. It will come on at the left-hand border or limb and disappear at the right, provided it remains so long. Now Wilson noticed that when a spot is near the limb the penumbra on the side nearest the sun's visual centre is hidden from our view, on the same principle by which, when looking into a silver jug, for instance, from one side of it, that interior which is nearest the eye is hidden from the view. In fine, he concluded, with perfect justice, that spots were pits or hollows with sloping sides, and we are justified in adding that they are cloud pits, and not caverns of solid matter.

These conclusions of Wilson have been abundantly confirmed by the Kew observers, Mr. De La Rue and his colleagues, and also by the spectroscopists who have devoted themselves to the sun.

It has furthermore been shown by these observers why the bottoms and sides, but more especially the bottoms, of such caverns should be blacker than the sun's ordinary surface. They are blacker because they are colder, and they are colder because they represent a down-rush of matter from the high and comparatively cold regions of the solar atmosphere—of some kind of celestial hail, we may perhaps imagine. So magnificent is the scale of operations that fifty or sixty of our own earths might be dropped into the cloud-cavern formed by the down-rush—at least in the case of large spots.

But a down-rush implies an up-rush, and we may add that a down-rush of matter comparatively cold implies an up-rush of

matter comparatively hot. We have abundant evidence of the existence of such up-rushes in the sun. Astronomers have been long familiar with the existence of two solar phenomena which occur together—*spots* and *faculæ*. Just as a spot represents something which is blacker, and therefore colder, than the ordinary solar surface, so a facula (torch) represents something which is brighter, and therefore hotter, than the surrounding regions. As I have said, faculæ and sun-spots accompany each other, and we have evidence from various quarters that the former are not merely high up in the solar atmosphere, but that they frequently represent matter in the very act of ascending, just as a sun-spot frequently represents matter in the very act of falling down.

If we turn now to those regions of the sun's disk in which there are no spots we do not find a uniformly luminous appearance. We find rather a fine mottled or granular surface consisting of certain bright patches and of others comparatively dark. The black patches may perhaps be regarded as very minute sun-spots, and the bright patches as faculæ on a small scale. Probably, too, the bright are up-rushes of comparatively hot, and the dark down-rushes of comparatively cold matter.

Thus we may imagine that the difference between a spotted and an unspotted portion of the solar surface does not consist so much in a difference in the kind of things there present as in their size. In the unspotted portion we have down-rushes and up-rushes side by side but on a small scale, while in the spotted region we have also down-rushes and up-rushes, but on a large scale.

It thus appears that a prominent characteristic of the solar surface is the presence side by side of gigantic up- and down-currents, the up-rushes consisting of very hot and very bright matter carried upwards from the heart of the sun, while the down-rushes consist of comparatively cold matter carried downwards from above.

We may add that this system of currents appears to be in all respects most powerful during periods of maximum sun-spots, at which times the velocities of solar matter are absolutely enormous. By a spectroscopic method we can estimate these velocities, and we find that on some occasions they reach the almost incredible speed of 150 miles per second.

As yet, however, we have only added another to the puzzles of solar physics. We began by expressing our astonishment at the power which the sun possesses of continuously pouring out vast quantities of heat and light, and we must now add to this our astonishment at the almost incredible velocity of its surface currents. We are thus presented with a couple of wonders instead of one; but is it not possible that the one of these may explain the other?

May not these gigantic currents denote the very machinery we are in search of, and in virtue of which the sun becomes able to carry light and heat from the interior to the surface, so as to give us a continuous and powerful supply?

The sagacity of the late Sir John Herschel was not behind in detecting the true state of the case. He suggested the probability that at times of maximum sun-spots the *sun-pot*, as he expressed it, may be in reality boiling very fiercely, and may therefore be giving us more of what we all want instead of less—be in fact preparing for a banquet instead of making arrangements for a famine.

Indeed we may be perfectly certain that the peculiar machinery which enables the sun to continue shining must be something which brings up with great promptitude to the surface new particles of hot matter from within, while it carries down with equal promptitude those that have already performed their light-giving office.

The sun is required to fire off without intermission a vast number of light- and heat-shots into space. And the battalions of particles that have done their work must quickly step behind to reload, while their places must be taken as quickly by a fresh and unexhausted levy of particles from within. Now this recruiting process, *which must exist*, can surely be nothing else than those violent up-and-down atmospheric currents which observation reveals to us on the surface of our luminary, and we are thus entitled, as a matter of speculation, to infer that our earth will probably receive peculiarly large supplies of sunlight on those occasions when there is most manifest disturbance on the surface of the sun. In fact we may regard the sun as a species of heat-engine. The ordinary conception of such an engine is that of something provided with cylinders, pistons, valves, wheels, and other mechanical appliances, the furnace and the boiler being kept generally out of sight; but the physical conception is something very different from this. A heat-engine, according to the physicist, is a machine having two temperatures: one being that of the source of heat, and the other that of the refrigerator: and it produces work while heat is carried from the higher to the lower temperature—from the source to the refrigerator, and not only so, but the faster the heat is carried the more work does it produce.

Here the object or end is to produce work, and the means employed is the carriage of heat. But if we regard the sun as an engine we may with propriety reverse this relation between means and end, and look upon the carriage of heat and light to the surface as the end aimed at, and the powerful surface-commotion as the means by which this end is accomplished.

I am by no means satisfied that we can fully explain why the currents on the sun's surface should be so very violent as observation proclaims them to be, but yet it is easy to see that the conditions there present are such as to favour the development of convection-currents of enormous power. Let us agree for a moment to study an ordinary furnace fire. We have here in the first place a carriage of hot air up the chimney which ultimately mixes with the cold air outside, while we have in the second an in-rush along the floor of the room of the cold air which feeds the fire, and which ultimately as hot air goes up the chimney and mixes with the cold air above. Now here we have a true convection-current, an up-rush of hot and an in-rush of cold air, and the more intense this current the more quickly will the fire burn.

It is easy to see in the first place why the hot air ascends the chimney. It does so because it has been expanded by heat, and is therefore specifically lighter than the cold air around it.

But why does a thing specifically lighter than the air ascend? Clearly on account of terrestrial gravitation. If there were no earth it would not ascend at all, and if the earth were less massive than it is it would not ascend so fast as it now does. Clearly then the draught of our chimneys depends upon the mass of the earth.

Again, the draught will depend upon the intensity of the fire, and also upon its size and that of the chimney, for it is obvious that an exceedingly small fire and short chimney would not draw well even though the temperature of the fire should be very high.

We thus perceive that the intensity of convection-currents depends—

1. On the temperature of the source of heat as compared to that of the cold parts of the arrangement.
2. On the force of gravity.
3. On the scale of the arrangement.
4. We may add that for strong currents it is necessary to have some substance, such as air, that expands greatly under an increase of temperature.

And furthermore such currents are still more augmented in violence by the presence of a condensable substance in the atmosphere, and are thereby rendered abrupt, and, to some extent, incalculable, in their operations, inasmuch as a small cause may produce a very great effect.

Now we have all these elements of power together on the sun's surface. For in the first place the intensity of the sun's heat is very great as compared with the cold of surrounding space. Secondly, solar gravity is very great, being about twenty-eight times greater than terrestrial gravity. Thirdly, the scale of the whole arrangement is very great; and lastly, the substance there present, gas and vapour, is one which expands greatly on being heated. On the sun's surface therefore all these causes of convection-currents exist in great strength; and if we bear in mind that they must be multiplied together rather than added we shall not fail to perceive how strong must be the effects which they will produce. Notwithstanding all this, it appears to me that we have more to learn with respect to the causes which produce the extraordinary violence of solar currents.

Although the series of sun pictures made by Schwabe is the first having pretensions to accuracy, yet Prof. Rudolph Wolf has endeavoured to render observations of sun-spots made at different times and by different observers comparable with each other, and has thus formed a list exhibiting approximately the relative number of sun-spots for each year. This list extends back into the seventeenth century, and is in many respects of much value.

By this means Prof. Wolf has shown that the eleven-yearly

period runs through all the recorded observations of sun-spots since the telescope came to be used. And furthermore it appears that these eleven-yearly oscillations are not always of the same magnitude; sometimes they are large, and sometimes small. They were probably small about the middle of last century, becoming large towards the end of it; they were again small about the early part of the present century. They have recently been large, and we may suspect that in future there will again be a falling off.

Besides exhibiting this complicated periodicity, sun-spots have many other characteristics, the most prominent of which I will now bring before you. Of these the most peculiar is a proper motion of their own. If there were no sun-spots it would be very difficult to determine the elements of the sun's rotation. Accordingly sun-spots have been used for this purpose ever since the telescope was invented. They are carried by the solar rotation from east to west across the visible disk of the sun in about thirteen days, and hence we may conclude that the sun, roughly speaking, rotates round its axis in twice thirteen, or twenty-six days. But Carrington found that spots move fastest when nearest the solar equator, and slowest when nearest the solar poles; and in consequence of this proper motion of spots there is an uncertainty as to the exact period of solar rotation. Another point of interest is the distribution of spots over the solar surface. There are never any at or near the sun's poles, the zone in which they break out having its limits about 30° on each side of the equator. It might be expected from this that we should have a maximum of spots close to the equator, but such is not the case. There are very few at the equator, the maximum number corresponding to a solar latitude of about 15° north or south. We must not however conclude that spots invariably exhibit a preference for this latitude, for Carrington has shown that on certain occasions they appear by preference to seek a higher latitude, widening out on each side of the solar equator simultaneously, while at other times they prefer a lower latitude, coming together towards the equator simultaneously on each side.

Dr. Smysloff of the Wilna Observatory has likewise observed a sort of hemispherical see-saw in the behaviour of spots. Sometimes they prefer the northern hemisphere of the sun—at other times the southern; but this observer is inclined to think that if we pursue our researches for a length of time sufficiently great we shall find an equal amount of spots in each hemisphere.

I have thus endeavoured to bring before you the fact that sun-spots exhibit curiously complicated laws of a roughly periodical nature. Two questions arise from this discussion: the one is of a theoretical nature, and has reference to the possible causes of this behaviour; while the other is of great practical as well as of theoretical interest, and has reference to the effect which these strange solar phenomena produce upon the magnetism and meteorology of the earth and upon the general well-being of the human race.

To be continued.

PROF. ALLMAN ON THE DEVELOPMENT OF THE CTENOPHORA

IN accordance with his usual practice of making his anniversary address at the Linnean Society an exposition of recent progress in certain departments of zoological research, the President on this occasion (24th May, 1881) selected as his subject the advances which, during late years, had been made in our knowledge of the development of the Ctenophora.

He referred especially to the beautiful researches of Alexander Agassiz, and to those of Fol, Kowalewsky, and most recently of Chun. He pointed out the phenomenon to which he was the first to call attention, that immediately after the earliest stages of the egg cleavage a remarkable peculiarity shows itself, in the fact that the continued cleavage is no longer uniform, but takes place much more energetically in certain cleavage spheres than in others, whereby the former are broken up into a multitude of small cells, which gradually envelop the latter, thus giving us at this early period of embryonic development the foundation of the two germinal leaflets, ectoderm and endoderm. He showed, how the body thus formed becomes excavated by an internal cavity, which soon communicates by an orifice with the exterior, thus presenting, as shown especially by the researches of Chun, the condition of a *gastrula*; how the gastrula-mouth becomes afterwards closed by the continued extension over it of the ectoderm; how a new orifice, the permanent Ctenophore-mouth, makes its appearance at the opposite hole, the ectoderm here becoming invaginated, so as to form the permanent stomach which opens into the central cavity, which becomes the "funnel" from which spring all the vessels which are destined to distribute the nutritive fluid through the body; how, in the spot formerly occupied by the gastrula-mouth, certain cells of the ectoderm become differentiated, so as to form the rudimental nervous system; and how the great vascular trunks are formed by the differentiation of portions of the endoderm, into which offsets extend from the central cavity.

Prof. Allman further referred to the facts connected with the metamorphoses which the larvæ of the Ctenophora undergo between the moment of leaving the egg and the attainment of the mature form—facts for which we are mainly indebted to the researches of Alexander Agassiz and of Chun. He showed how the lobed section of the Ctenophora, as proved by the investigations of A. Agassiz on *Bolina*, and by those of Chun on *Eucharis*, are at first quite destitute of the "lobes" which constitute so characteristic a feature in the adult; and how the young Ctenophore has at this time all the characters of the more simply constructed Cydipidæ, *Eucharis* being also compressed like a *Mertensia* in the direction of the stomach axis, while in the adult the compression of the body is at right angles to this; how the lobes afterwards grow out laterally from the oral side of the body; how the meridional vessels at first ending in blind extremities extend themselves into the rudimental lobes, and there form the anastomoses and rich convolutions which become so striking in the adult, the stomach vessels finally entering into the anastomoses.

He also referred to Chun's remarkable discovery of the sexually-mature condition of the very early larva of *Eucharis*, from which was reared a young brood which returned to the larvæ form from which it originated.

Chun's observations on the metamorphoses of the Venus's girdle (*Cestum Veneris*) were also dwelt on. It was shown how the young cestum had a nearly globular form, and possessed all the essential features of the Cydipidæ, so that notwithstanding the extremely aberrant characters of the adult the young may be taken as affording a type of the gastro-vascular system, with the distribution of the vessels in the Ctenophora generally. The gradual extension of the Cydippe-like larva in the direction of the funnel-plane changes it into the long, flattened, band-like form of the adult, and brings about (with modifications in the number and direction of the swimming-plates, and the substitution of new tentacles to replace those of the larva which had disappeared) the singularly aberrant course of the vessels characteristic of the mature Venus's girdle.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—Mr. J. W. Clark is to be re-appointed Superintendent of the Museums of Comparative Anatomy and Zoology for two years, at the end of which time the Council of the Senate appear to anticipate that some fresh arrangements as to this office may be made.

Mr. W. Hillhouse, Assistant Curator of the Herbarium, will give a course of lectures on Morphology and Systematic Botany during July and August, suited to candidates for the Natural Sciences Tripos. In connection with the course there will be practical work in the Gardens and Botanical Laboratory; and a botanical excursion will be made, weather permitting, on Wednesday in each week.

DUBLIN.—The Professors of the Medical School in Trinity College have, at the suggestion and with the sanction of the Rev. Dr. Haughton, the senior lecturer of the College, introduced into their summer courses of lectures, to a very large extent, practical instruction, instead of the time-honoured and now somewhat antiquated series of prelections. These summer courses chiefly consist of Chemistry, Histology, Botany, Comparative Anatomy, and Operative Surgery. In the Chemistry, instead of listening as formerly to an hour's lecture three times each week, the students work in the laboratory under the superintendence of Prof. Emerson Reynolds, F.R.S., for two hours every alternate day, and on one day in each week attend a demonstration by the Professor on the analysis of water, air, and articles of food. In the Histology Prof. Purser gives a lecture on one day in each week, at the close of which illustrative preparations are shown in the laboratory. On the other days the students are engaged on practical work in the new physiological laboratory, where, as in the chemi-

cal laboratory, each student has his own place, with full set of apparatus and reagents. The laboratory is open from 11 a.m. to 5 p.m. In Botany, Prof. E. Perceval Wright gives the first ten lectures to the class in the lecture-room, on the general details of the structure and morphology of flowering-plants. The second part of the course consists of ten demonstrations on such forms as Bacteria, Yeast-mucor, Saprolegnia, Oidium, Mushroom, the Algæ; and the remaining portion is given in the College Botanical Gardens, when each student is required to have a practical acquaintance with a certain number of natural families. The demonstrations in Comparative Anatomy are conducted by Prof. Macalister, F.R.S., who is fortunate in having the resources of the gardens of the Zoological Society to assist in the practical work of his class. So far as the experiment has this session gone, the results have been most happy, the students showing a far greater interest in their work, and the demonstrations being less formal than the lectures, they have greater facilities for asking questions.

THE fiftieth anniversary of the foundation of the Technische Hochschule at Hanover is being celebrated during this week. Numerous guests from all parts of Germany, as well as from England, Sweden, Norway, the Netherlands, and Russia have arrived at Hanover.

SCIENTIFIC SERIALS

Journal of the Academy of Natural Sciences of Philadelphia, vol. 7, second series, part 4, 1874–1881.—Wm. M. Gabb, descriptions of Caribbean Miocene fossils; descriptions of new species of fossils from the Pliocene clay-beds between Limon and Moen, Costa Rica, together with notes on previously known species from there and elsewhere in the Caribbean area (with four plates).—Andrew Garrett, on the terrestrial mollusca inhabiting the Cook's or Harvey Islands.—Dr. C. Chapman, the placenta and generative apparatus of the elephant (with three plates).—Dr. Joseph Leidy, on some parasites of the Termites (gives full descriptions, with figures, of the strange forms briefly described in the *Proceedings* of the Academy of Natural Sciences, Philadelphia, for 1877. *Trichonympha agilis* is a truly extraordinary form, possibly a protozoan intermediate between the Gregarines and Infusoria).—Dr. Joseph Leidy, remarks on *Bathygnathus borealis*.

Zeitschrift für wissenschaftliche Zoologie, Bd. 35, Heft 3, 1881.—Dr. J. W. Spengel, the organ of smell and nervous system in the mollusca, a contribution to our knowledge of the unity of the molluscan plan (plates 17, 19).—Dr. O. Bütschli.—Short contributions to a knowledge of the Gregarines: (1) on the development of *Gregarina* (*Clepsidrina*) *blattarum*; (2) on the power of adhering in *Monocystis magna*, and on the pseudonavicella in the monocysts of the earth-worm; (3) on some egg-shaped Psorospermia in the intestine of *Lithobius forficatus* (plates 20, 21).—Prof. F. E. Schulze, researches on the structure and development of sponges, x. On *Corticium candelabrum*, Schdt. (plate 22).—Dr. A. Gruber, on the process of division in *Euglypha alveolata* (plate 23).—B. Ulianin, on the development in amphipods (plate 24).—Dr. Paul Fraisse, on molluscan eyes with an embryonal type (plates 25 and 26) (Patella, Haliotis, Fissurella).—Dr. P. A. Loos, on the albuminiferous glands in amphibia and birds (plate 27).

Atti della R. Accademia delle Scienze Fisiche e Matematiche, Napoli, vol. vii.—F. Panceri, the phosphorescence and the phosphorescent organs in some Annellida (Chætopterus, Balanoglossus, Polynoe), plates 1 to 4.—On the seat of the phosphorescence in some Campanularia (with a plate), and observations of some new species of marine nematoid worms (*Desmoscolex elongatus* and *D. lanuginosus*, *Echinoderes meridionalis*, *E. minutus*, *E. eruca*, and *E. spinosus*, *Tristicochæta inarimense*, n.gen. et n.sp. near Chætosoma); all the new species are figured.—A. Costa, notes of a visit to Egypt, Palestine, and the coasts of Turkey (zoological).—V. Cesati, on a new species of Battarræa (*B. Guicciardiniana*), with a plate.—On a collection of Pterydophytes made at Borneo by Signor D. Beccari, with 4 plates.—G. Licopoli, on the fruit of the vine and its chief constituents, with a plate.—G. A. Pasquale, on a new species of Lonicera (*L. stabiana*), with a plate.—F. Gasco, account of the whale (*Balæna Biscayensis*, Esch.) captured at Taranto on February 9, 1877, with 9 plates.—G. Battaglini, on projective geometry.—E. Fergola, on the dimensions of the earth.—G. Nicolucci, the Cola grotto near Petrella di Cappadocia, in the province of Abruzzi, with three plates of animal remains.—On prehistoric researches about the environs of the Lake of Lesina.—L. Palmieri, on the present condition of electrical meteorology.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 12.—"Investigations on the spectrum of magnesium," by Professors Liveing and Dewar.

The flame of magnesium burning in air shows strongly, generally well reversed, the line at wave-length 2850 (Cornu); a strong triplet, resembling in the relative distance of its lines the other magnesium triplets, close to the solar line M; the well-known triplet near L; and a remarkable series of lines and bands, generally resembling the spectra of some compounds, extending from M to between L and K. Neither the strong triplet at M nor this series of bands are represented in the spectrum of magnesium either in the arc or spark. These flame-lines are remarkable as further evidence of the power of substances to emit, at comparatively low temperatures, radiations of short wave-length.

In the arc the authors notice a series of triplets, of which the least refrangible lines have wave-lengths about 2767, 2736, 2798, 2673, 2649, 2633 respectively. These, with the well-known triplets *b*, and those near the solar lines L, P, and S, form a series, similar to those described by the authors in the spectra of sodium, potassium, and lithium, in which the alternate members are sharp and diffuse, and succeed one another at shorter and shorter intervals in a way which indicates that they follow a definite law and are probably harmonically related, though not forming a simple harmonic series. They observe that the line w.l. 2850 is the strongest line of magnesium both in the flame and arc, and one of the strongest in the spark, and that it is nearly the octave of the line some time since observed by them at wave-length about 5710. They observe in the arc only the strongest two of the quadruple group described by Cornu from the spark at wave-lengths 2801, 2795, but they notice both in arc and spark a group of five lines a little higher at wave-lengths about 2782, 2781, 2779, 2778, 2777. All these lines, including the diffuse members of the series of triplets, they have often observed reversed when the arc is taken in one of their crucibles. The line w.l. about 4570, so conspicuous in the flame, first noticed by the authors in the spark, is well seen and easily reversed in the arc, and they believe it to be represented in the solar spectrum by the line w.l. 4570·9 in Ångström's map. Besides these lines they observe in the arc a pair of lines slightly less refrangible than the pair in the spark, described by Cornu near the solar line U. In the spark they observe two pairs of ghost-like lines below the triplet near L, which together with the fainter two of the quadruple group (2801, &c.), seem to suggest the possibility that some of the particles of magnesium have, owing to particular circumstances, their tones a little flattened in regard to these particular vibrations, though the constancy in the amount of displacement of the lines militates against such an hypothesis.

In regard to the *b* group, observations on the spectrum of the fourth order given by a Rutherford grating of 17296 lines to the inch showed that the iron line in b_4 is a little less refrangible than the magnesium line. The additional lines near this group observed by Fievez they ascribe to a periodic inequality in the ruling of the Rutherford grating, arising from an imperfection of the screw of the ruling machine, which produces a series of *ghosts* on either side of each principal line. The positions of these *ghosts* have been investigated mathematically by Peirce (*Math. Journal* of John Hopkins University), and observations of them tally with the theory. They are embarrassing in the case of bright lines, but may be detected by their changes of position in the spectra of different orders.

The magnesium-hydrogen spectrum which the authors have previously investigated and found to be produced at ordinary and reduced pressures when both elements are present, but not otherwise, they have now investigated further by observing the spark discharge between magnesium poles in hydrogen, nitrogen, and carbonic oxide, at pressures varying from one to twenty atmospheres. They find that in hydrogen, when no Leyden jar is used, the peculiar fluted spectrum of magnesium hydrogen is much more brilliant at higher pressures, becoming fully equal in brightness to the *b* group, notwithstanding the increase in

brilliance of that group by the higher temperature of the discharge in the denser gas, while the other lines of magnesium fade, and even the hydrogen lines C and F are invisible. This disappearance of the hydrogen lines they ascribe to the large quantity of magnesium carried over in the spark. When a Leyden jar is now connected with the coil the fluted spectrum continues bright for some time, but gradually fades as the continuance of the high temperature sparks decomposes the compound. In nitrogen the flutings are only seen at first, probably from hydrogen occluded, as is usually the case, in the magnesium, and disappear when the pressure is increased, and cannot be made to re-appear either by reducing the pressure or varying the discharge. In carbonic oxide the behaviour is similar. The authors conclude that the production of this spectrum is dependent on a combination of the two elements, and is not merely a matter of temperature. They describe this spectrum as consisting of three parts, a group of three sets of flutings in the yellow commencing at about the wave-lengths 5618, 5566, 5513; a group of two sets of flutings in the green commencing at about w.l. 5210, and close to *b*; and a group of two blue bands with their less refrangible edges at about w.l. 4849 and 4803 respectively. The authors differ from Ciamician, who has figured this spectrum, in regard to the number of flutings in the green and blue. This spectrum can be well seen when sparks are taken from a solution of magnesium chloride in a tube full of hydrogen.

After simplifying the spectrum of magnesium by separating that of magnesium hydrogen, and supposing the triplets to be harmonically related, and perhaps some of the single lines similarly related, there are still a greater variety of vibrations than any very simply constituted particle could be expected to be capable of assuming.

Linnean Society—Anniversary Meeting, May 24.—Prof Allman, LL.D., F.R.S., president, in the chair.—There was a very numerous attendance of the Fellows.—The Treasurer (Mr. Frederick Currey) read his Annual Report, stating that financially the Society continued prosperous. The invested capital at the present date is 3868*l.* 4*s.* 6*d.*, the sum of 140*l.* derived from Fellows' life compositions during the past twelvemonth having been invested in consols. The balance at the bankers at the end of the financial year (April 30) was 532*l.* 10*d.*, and at the bankers' and on hand at this date (May 24) 604*l.* 15*s.* 10*d.* The annual contributions amounted to 928*l.* 4*s.*, and sales of publications 230*l.* 19*s.* 7*d.*; there was an increase in the admission fees, and decrease in compositions. 104*l.* 8*s.* 3*d.* had been expended on the purchase of books for the library, and 48*l.* 1*s.* 11*d.* towards bookbinding and stationery; 765*l.* 18*s.* 2*d.* had been spent on the Society's publications. A handsome donation of 50*l.* had been made by Mr. G. Bentham.—The Secretary (Mr. B. Daydon Jackson) then read his Report. Since the last anniversary eleven Fellows of the Society had died and four had withdrawn. Against this thirty-seven new Fellows had been elected, besides one Foreign Member and one Associate. During the past year there had been received as donations to the library 106 volumes and 125 pamphlets and separate impressions of memoirs; from the various scientific Societies there had also been received in exchange ninety-six volumes and 248 detached parts of publications, besides twenty-three volumes of donations from the editors of independent periodicals. There had been purchased 90 volumes of importance, among these 63 serials, equal to 10 volumes, the total additions to the library therefore being 315 volumes and 373 separate parts. Mr. Kippist had presented framed water-colour sketches of Dr. Robert Brown's birthplace, London residence, and Sir J. Banks's library. The Society's collections and herbaria had been duly examined and reported on to the Council as in good condition. After a service of fifty years Mr. Kippist had resigned his position as librarian to the Society, and the Council, in acknowledgment thereof had granted him a retiring pension.—Mr. Baker, in the name of Mr. J. W. Miers, then presented to the Society a portrait of his father, the late John Miers, as a memento of his connection therewith, and Prof. Allen Thomson as representative of a small committee also presented the portrait of Prof. St. George Mivart, late Zoological Secretary, to the Society.—Prof. Allman then delivered his anniversary address, the subject chosen being "Recent Advances in our Knowledge of the Development of Ctenophora."—The Secretary afterwards read obituary notices of the several Fellows that had died during the year, making special mention of the life and labours of Mr. G. R. Alston, the late lamented Zoological Secretary, Mr. John Gould, the ornithologist, Mr. Gerard Krefft, of Sydney, Dr. J. Lauder Lindsay, and Mr. R. A. Pryor, of Herts.—The scrutineers having examined the ballot, then reported that Mr. Alfred W. Bennett, Mr. Francis Darwin, Prof. E. R. Lankester, Sir John Lubbock, and Mr. Geo. J. Romanes had been elected into the Council in the room of E. R. Alston (deceased), Dr. T. Boycott, Prof. M. Foster, Dr. J. Gwyn Jeffreys, and Prof. St. George J. Mivart, who retired; and for officers Sir John Lubbock was elected president, Mr. F. Currey, re-elected Treasurer, Mr. B. Daydon Jackson, re-elected Botanical Secretary, and Mr. G. J. Romanes was elected Zoological Secretary.

Zoological Society, May 17.—Dr. A. Günther, F.R.S., vice-president, in the chair.—Mr. Sclater exhibited and made remarks on examples of four parrots of the genus *Chrysotis* from various islands of the Lesser Antilles.—A communication was read from Mr. Carl Bock, in which he gave an account of the land- and fresh-water shells collected in the highlands of Padang, Sumatra, and in the eastern and southern parts of Borneo during his travels in those districts. Eight new species were described.—A communication was read from Mr. G. B. Sowerby, jun., containing descriptions of eight new species of shells from various localities.—Mr. W. A. Forbes read a paper on the anatomy and systematic position of the Jacanas (*Parridæ*), which he showed were in no degree related to the rails, but form a separate group, to be placed amongst the plovers and allied birds (*Limicolæ*). The author also called attention to the peculiar form of the radius in the genus *Metopidius*, which is not developed in the other genera of this group.—A communication was read from Mr. L. Taczanowski, C.M.Z.S., containing the description of a new species of weasel from Peru, proposed to be called *Mustela Jelskii*, after its discoverer.—A communication was read from Mr. W. F. Kirby, containing a description of the hymenopterous insects collected in Socotra by Prof. Bayley Balfour. Of these two were apparently new to science.—A communication was read from Mr. Francis Day, F.Z.S., containing remarks on the range of *Apogon Ellioti*.

Royal Microscopical Society, May 11.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—Ten new Fellows were elected and nominated.—Amongst the objects exhibited were Seibert's polarising microscope, Nachet's binocular dissecting microscope, Verick's skin microscope, Houston's botanical microscope, embryological sections from the Naples Zoological Station, &c.—Papers and notes were read on a new and remarkable annelid (Mr. Stewart); the markings of diatoms (Dr. Matthews, Mr. J. Deby and Count Castracane); a new species of *Hydrosera Wallich* (Dr. Stolterforth); and improvements in illumination (Mr. J. Smith); also a note by Prof. Abbe on the conditions of micro-stereoscopic vision, with special reference to the fact that the lineal amplification of an object in depth is equal to the square of the lineal amplification in breadth, reduced, however, in proportion to the refractive index of the medium in which the object is: thus an object under a power of 100 times would be magnified 10,000 times (lineal) in depth if in air, 7500 times if in water, and 6600 if in oil or balsam.

Edinburgh

Royal Society, April 4.—Prof. Fleeming Jenkin, vice-president, in the chair.—In the absence of the author, Prof. Alleyne Nicholson read a descriptive note by Dr. Carmichael McIntosh on the Phoronis, one of the specimens obtained in the dredging operations of the *Challenger*. This *Annelid* was of special interest as indicating in several particulars close similarity to certain well-known *Coelenterates*.—Dr. R. H. Traquair read a paper on additional researches on the structure of the *Palæoniscidæ* and *Platysomidæ*. The more that the fossil remains of these families were studied the more difficult did it become to clearly differentiate them from each other; and from his later researches Dr. Traquair had been obliged to adopt a wider definition of *Palæoniscidæ* than he had formerly employed. Hence it appeared that the criticism that had been urged against his former papers, viz., that he had not shown sufficient ground for their separation as two distinct families, could still be urged with even greater reason; but this, according to the doctrine of descent, was a natural consequence of increased information. Certain of the specimens he had examined, though retaining the most essential characteristics of either family, as the case might be, possessed modifications of structure which were ordinarily typical of the other. The evidence was that the

Platysomidæ had been derived from the *Palæoniscidæ*.—Prof. Tait communicated a number of results of experiments on the heating effects of compression—experiments that had been suggested by his recent inquiry into the pressure errors of the *Challenger* thermometers. Specimens of various substances, such as raw potato, raw flesh, cheese, pith, bar-soap, liquorice, cork, india-rubber, &c., were compressed suddenly in a hydraulic press. The rise of temperature was measured by means of a thermoelectric junction set into the heart of the material, and connected to a delicate galvanometer in a contiguous room. After the heat evolved by the compression had diffused itself, so that the galvanometer came back nearly to its old zero, the pressure was suddenly relieved, and the heat absorbed in the return of the substance to its original bulk was measured by the reverse current produced. In most cases this cooling effect was exactly equal to the original heating effect. Cork however, which rose in temperature 1°·3 F. for one ton's weight increase of pressure, fell in temperature only 0°·9 F. on removal of the pressure—a result in striking accordance with the well-known sluggishness of cork in recovering its original bulk after withdrawal of the pressure that had compressed it. In this particular, india-rubber, whose temperature was raised about 1°·5 F. for the same increase of pressure, was markedly opposed to cork. Potato and raw flesh both indicated about the same rise of temperature—0°·7 F. Pith, again, which resembles these in the large percentage of water that enters into its constitution, was raised in temperature only 0°·37 F., giving no perceptible difference of effect over what would have been produced by water alone.

PARIS

Academy of Sciences, May 23.—M. Wurtz in the chair.—The following papers were read:—On the old Observatory of Cairo, by M. de Lesseps. This observatory no longer exists; but M. de Lesseps, in a letter here given, urges its restoration on the Khedive. It is stated that the Egyptian Institute in Cairo has received the *Connaissance des Temps* complete from 1679 to 1866.—Nebulæ discovered and observed at the Observatory of Marseilles, by M. Stephan.—On the genera *Williamsonia* Carruth., and *Goniolina* d'Orb, by MM. de Saporta and Marion.—On an experimental process for determining the sensibility of the retina to coloured luminous impressions, by M. de Grandimont. The observer looks steadily at the central point of a disk having apertures, beyond which coloured surfaces are placed. By degrees the sensation of colour is extinguished. On suddenly putting white surfaces in place of the coloured, the complementary colours come out with great brightness and purity. The instrument is named a *chromatroposcope*.—Barometer based on the equivalence of heat and pressure on the volume of a gas, by M. Decharme. It consists simply of an ordinary alcohol or mercury thermometer, and an air thermometer to show the volumes of gas corresponding to the temperatures observed. To find the atmospheric pressure, the data of these instruments are interpreted by the aid of curves and tables previously prepared.—On a cryptogam insecticide, by M. Lichtenstein. This is a *Botrytis* (same genus as that which infests the silkworm), found to have killed all the aphidians on a cineraria in the Jardin des Plantes at Montpellier. It operates only in the hothouse, and M. Lichtenstein could not inoculate either phylloxera or other plant-lice with it in open air.—On the geometry of spheres, by M. Stephanos.—On Fuchsian functions, by M. Poincaré.—The standards of weights and measures at Paris Observatory and the apparatus used in their construction; their origin, history, and present state, by M. Wolf. This note relates chiefly to the toise du Perou and du Nord (so called), which the author considers to be now in the same state as when they came from the hands of Langlois in 1735.—On the law of radiation, by M. Violle. This law may be represented between 0° and 1775° by the formula $I = mTb^{T^2}a^T$, where T represents the absolute temperature, m a constant coefficient, b the number 0·9999938, $a = 1{\cdot}03550 - 13\lambda$, λ being the wave-length in millimetres.—On the production of sound by the force of radiation, by Prof. Ball.—On radiophony; thermophone reproducing the voice, by M. Mercadier. Light is reflected from a plate of silvered glass, behind which is a small air reservoir, with a thin plate of mica or caoutchouc, which receives the voice through a tube. At the receiving-end, one of the author's small glass tubes, with as smoked piece of mica and ear-tube, is brought where the light is concentrated by a lens or concave mirror. With this arrangement speaking was distinctly, though faintly, heard at about 20m. distance, the windows of the speaker's room being closed.—On the same subject, by the same. A long tube (10m.) may be used by the speaker. Electric light and (less easily) oxyhydrogen light, gave the effects. Solar radiations act best when hottest. Alum solution interposed reduced the effects considerably; with a thin ebonite plate they were weakened, but still distinct; similarly with plates of tinsel of zinc, copper, aluminium, &c., $\frac{1}{10}$mm. to $\frac{2}{10}$mm. thick.—Modification of the Neef interrupter for the Ruhmkorff coil, by M. Ducrétet. The vibrating slip is lengthened and its two ends fixed to two columns; the small soft iron mass in the middle. The vibrations are very rapid; the spark is modified, becoming continuous, more powerful, and hotter.—On the rotatory power of artificial codéine, by M. Grimaux.—On the proportion of carbonic acid contained in the air, by MM. Muntz and Aubin. This gives results of observation, by a method formerly described, at Paris and a station in the country. They appear mainly to confirm M. Boussingault's and M. Reiset's results. The proportions of CO_2 in normal air vary within but narrow limits. In the environs of Paris, whatever the direction of the wind, figures were got closely similar to those of M. Reiset near Dieppe.—Preliminary study of reactions without the intervention of a solvent, by M. Lorin.—On silicomolybdates, by M. Parmentier.—Action of ammonia on chloride of isobutylene, by M. Oeconomidés.—On some points relative to the organisation and the development of Ascidians, by M. Van Beneden. This relates to his observations at the Naples station in April last. The development of Ascidians does not (he considers) warrant the radical distinction drawn by the brothers Hartwig between a mesoderm and a mesenchyme.—The vessels of the ink-bag of cephalopoda, by M. Girod.—On the troubles of sensation produced by cortical lesions of the brain, by M Couty. The observations were upon apes and dogs. Anæsthesia, when it occurs, affects the side opposite that of the cortical lesion, and for touch, as for vision, is always incomplete. It is rare, and it has no relation to the place or extent of the cortical lesion. These troubles of sensibility have no necessary connection with other troubles.—Mechanism of infection in different methods of inoculation of symptomatic *charbon*; application to the interpretation of clinical facts and to the method of preventive inoculations, by MM. Arloing, Cornevin, and Thomas. An abortive *charbon* may be given by inoculation in the veins, in the connective tissue, or in the respiratory passages.—M. Richard announced the discovery of a cavern in the mountain of Ayuso (Segovia), containing a large number of prehistoric *débris*.

THURSDAY, JUNE 9, 1881

THE STEPHENSON CENTENARY

GEORGE STEPHENSON was born June 9, 1781. The importance of this event to us who now inhabit civilised countries is certain; for whatever view we may take as to the inevitability of railways, it is matter of history that for twenty-five years—1815 to 1830—after Stephenson had to all intents perfected the system of railway and locomotive, which still holds its own, no other engineer or competent mechanic went even so far as to admit its merit. It is therefore to George Stephenson that we are indebted for our existing railways, for the immense extension of mechanical contrivance which has followed in their train, and for all that these have done for us in the way of improving the circumstances of life.

As the custom of centennial celebrations has become almost universal, it would partake of irreverence to allow the hundredth anniversary of the birth of one who has given us so much to pass unnoticed. But in what form can we celebrate such an event? No oratory can remind us of Stephenson's name when we continually hear the puffing of his engine. What monument can compare with the cuttings and embankments seen whichever way we turn? In truth Stephenson's works are ever before the eyes and sounding in the ears of all people. We have no political or social purpose to serve by a national ceremony. Killingworth or Newcastle will have its dinner and, as we understand, the intention is that some money should be subscribed for an educational foundation. This is all very well, but it is confined to a few who take a special interest in the place, and is no measure of that universal offering to the memory of our hero which goes up, not once in a hundred years, but hourly.

To the readers of NATURE who are not only of the travelling public, but to whom doubtless the works of Mr. Smiles are familiar, anything we can say as to the life and work of Stephenson must seem totally inadequate. But not to let the occasion pass we will endeavour, by reference to some of the features of Stephenson's work, to illustrate a thought which has recurred to us with ever-increasing force when considering the works of those who have pioneered the way in practical mechanics. This thought may be expressed somewhat as follows:—That if we are to accept the proved ability to predict results with certainty as conclusive evidence of a knowledge of the laws and principles on which these results depend, then it is evident that acute observation of mechanical and physical phenomena does lead to a very clear insight into the laws and principles involved, although the observer may be—generally has been—altogether unable, save by the prediction of results, to give definite shape to his abstract ideas, and much more to give them articulate expression. And further, that this apprehension of principles, acquired by the observation of the dependent phenomena, is the only real apprehension, and is a very different thing from that knowledge or conviction of the truth of principles which comes from reading or argument, and which, however useful for purposes of criticism, rarely if ever leads to a prediction.

In the instance of Stephenson we have a perfect example. He received absolutely no education except by his own observation of the animals and other works of nature in the vicinity of his dwelling, and the rude mechanism of the surrounding collieries. Such too were the exigencies of his existence, that although he was assiduous in the task of self-instruction, as in all other things, in 1815, at the age of thirty-four years, and at the very time when he was making his first engines, "Blucher" and "Puffing Billy," the first of a race destined to overrun the earth and create the greatest of all revolutions, though he could read and write he had not as yet mastered the rule-of-three. Yet in the construction of these very engines he showed his confidence in results, the prediction of which shows that he had acquired an insight into principles which were entirely unexpressed at that time, and as regards some of which their expression is still incomplete.

Amongst the mechanism of the railway, almost every detail of which was conceived by Stephenson, there are certain details or features which, with a view to rescue them from being altogether claimed for other inventors, the friends of Stephenson have ever marked as bearing more distinctly the impression of Stephenson's hand. These are the smooth driving-wheel, the chimney blast, and the multitubular boiler. This is as it should be.

But, as it seems to us, in thus bringing into prominence the special features of Stephenson's system, Stephenson's friends have effectually diverted attention from that which is of far more importance. Thus, although it has never been claimed for Stephenson that he was the first to use smooth driving-wheels, Trevithick and Hedley having been obviously before him, it is contended that Stephenson consistently from the first maintained the sufficiency of the adhesion, while the others invented "imaginary difficulties" which led them to contrive all sorts of means of preventing the wheels of their locomotives from slipping. This view of the matter is however essentially wrong, and is unfair to both sides, for on the one hand, while there is no evidence to show that Trevithick or Blenkinsop ever ignored the tractive power of smooth wheels, neither is there any evidence to show that Stephenson ever maintained that the adhesion of smooth wheels would suffice to accomplish that for which the rack was being used. Had he done so he would have been wrong. But, on the contrary, there is ample evidence to show that Stephenson clearly perceived—that at the very onset he determined by careful experiment—the limit of the adhesion of his smooth wheels, and that he never attempted to use them except on a level road. The question at issue is much broader and more important than that of mere mechanical contrivance. It was as to how far the locomotive should be set to the task of the horse in drawing its load over the hills and valleys, and how far the hills should be cut down and the valleys filled up.

This, the level road, the very form of the railway, was Stephenson's main idea. And it was his foresight and determination in respect of this that made his railways a success from the first. His experience and observation had led him to perceive what all subsequent experience has confirmed, that the locomotive, in virtue of its size and clumsiness, could only be usefully employed on a nearly level railway. He did not actually maintain that

it would be impossible to make a machine that would travel on common roads and even mount hills, but "even suppose that such a machine could be constructed to carry twenty or thirty passengers at ten miles an hour, put it on a level railway and it would carry 200 or 300 passengers at thirty or forty miles an hour."

In his first colliery railways at Killingworth and Hetton he laid the lines in a series of flat reaches separated by inclines, and working the inclines by fixed engines, confined the functions of the locomotive to drawing the waggons along the flat reaches. It was this insistence on the level road that enabled him to use smooth wheels, and not that he had discovered any adhesion previously unknown or that others had overlooked.

Stephenson's position was a nearly level line at any price on which the adhesion of the wheels is sufficient as against a road following the slope of the country, for which, according to his view, by whatever means the adhesion might be increased, the iron horse was ill adapted. In the clear conception of the importance of this level road, coupled with his determinate insistence in carrying out his view, no matter what the difficulty—the veritable removal of mountains—have we not the best of all proof that, however unconsciously, he was guided by a perception of that law which connects the limits in size and activity of structures, with the strength of the material of which they are composed. And by which law we may now perceive that it is only by smoothing the road and so reducing the call for strength and power that we have made our machines to exceed in size and speed the limits which Nature had reached in her animals.

Into another law, called the Conservation of Energy, there can be no doubt that Stephenson had an insight far beyond his time. He saw that the conveyance of a load was not a question of force, but of the product of force into the distance traversed, and that however great might be the tractive power of his engine, its speed must depend on the ratio of the rate at which steam could be generated to the load. So long therefore as the tractive power was so large as—compared with the steam-generating power of his boiler—to prevent his engine, when fully loaded, travelling at more than ten miles an hour, he could gain nothing by increased adhesion. But, on the other hand, in his first engine the desideratum was increased steam-generating power for the same weight of boiler.

With, as Robert Stephenson has told us, the direct object of accomplishing this, George Stephenson turned the exhaust steam in the form of a jet or blast up the chimney of his second locomotive, "Puffing Billy." If this is so, and there appears no evidence to the contrary, it was a prediction with regard to the motion of fluids, for the making of which there is as yet no established law in the theory of hydrodynamics. That the result is such as was here predicted, or that a jet of steam or of air playing at high velocity along the interior of an open-ended tube does impart motion to the air within the tube and causes a current, is of course now well known, but our present knowledge is derived from the experience of the locomotive chimney. There is no evidence that it was known to any one before 1815, nor indeed has there been found any other mechanical purpose of general importance in which the same action could be usefully employed. Neither in the stationary engine nor yet in the marine engine has it proved economical. Thus the locomotive and its offspring, the portable engine, were the only machines possessing this organ.

Although it has been the custom for writers on the steam-engine to speak as though the manner of action of the blast were self-evident, this only shows that these authors have not understood it—indeed how should they? The general law on which the action of the blast depends is that a jet of fluid issuing into surrounding fluid at rest will not, when it has more than a certain velocity, proceed in a straight vein or column, but begins at once to wriggle, and as it advances involves itself in an extremely complex manner with the surrounding fluid, with which it shares its forward momentum. It is only during the last few years that the generality of this action and the circumstances on which it depends have attracted attention, and the completeness with which the action has been overlooked is shown by the numerous attempts that have been made to invent fanciful explanations of the following phenomenon. When a jet of steam, say half an inch in diameter, issues from a high-pressure boiler, as from a gauge cock, although the steam itself must have the temperature of boiling water, still the hand may be held in the jet at a distance of two or three inches from the cock without any inconvenience. How has the temperature of the steam become lowered? is the question for the answering of which numerous hypotheses have up to quite recently been invented. The answer is that the temperature of the steam does not become lowered, any more than the strength of the mustard in a sandwich, but that the steam has involved within its column layers of cool air, sandwich fashion, and as the combination rapidly passes the same point of the skin, the sensation produced is that of the mean temperature of the air and steam.

It is on this action of a jet to mix itself up with the surrounding medium that the draught produced by the blast up the chimney depends, and Stephenson's confident prediction of this draught is the best evidence that observation had led him to a perception of the more general action.

Considering the capacity of the man as shown by his other work, it would have been a matter for surprise had not Stephenson acquired a unique knowledge of the phenomena of fluid motion. He had the best opportunity for observation—his whole time had been spent in the care of pumps, pumping-engines, and the arrangements for ventilating and draining mines. His habit was to bring all his ideas at once to the test of experiment; and in devising his safety-lamp he had carried out a very careful series of experiments on the behaviour of jets and the rate of their admixture with the surrounding air.

Although, as shown by the employment of the multitubular boiler, Stephenson's mechanical insight does not perhaps stand out in so very clear a light, inasmuch as he made this step at the suggestion of Mr. Booth, still it cannot have been fortuitous that in adopting these small tubes he should have at once introduced all those conditions on which their employment is alone successful.

That small tubes of the same aggregate capacity as a single flue afford greater cooling surface for the hot gases is indeed obvious, but it was Stephenson's own observation that taught him that such increase was desirable,

while the fact that the gases in passing through the small tubes would encounter much greater resistance than in the single flue rendered the successful employment of the multitubular boiler dependent on the increased action he could give to the blast. However in all respects he came out right in the very first trial.

In the "Rocket" he had a self-moving machine, which resembled the moving animal not only in the fact that they both derived their power of motion from the combustion of carbon, but the physiology of the machine resembled that of the animal system in that essential particular which connects the action of the heart and lungs with that of the muscles, so that any demand upon the activity of the latter is at once met by increased activity in the former. In the locomotive the law of adjustment is perfect. Whatever the load within the limit imposed by the adhesion of the wheels, and whatever the speed, the stimulating action on the fire is sufficient, and no more than sufficient, while in all cases the tubes are sufficiently long, and no more, to pass the heat generated into the boiler.

The functions of the locomotive engine more nearly correspond with the functions of moving animals than do the functions of any other machine, and hence it was essential that there should be a correspondence between the organisation of the locomotive and that of working animals, which correspondence may be dispensed with in other engines. Is it not probable, we ask, that he who produced the locomotive physiologically complete had been guided, however unconsciously, by the truth of his observation of those animals which his machine was to set free from their task? OSBORNE REYNOLDS

THE HISTORY OF SALT

The History of Salt. By Evan Marlett Boddy. (London: Baillière, Tindall, and Cox, 1881.)

THIS book is quite a literary curiosity: the author hopes, and not without reason, that it will be found to afford amusement. Mr. Boddy we take to be a medical student, and it is a kindness to him to suppose that he is young. After reading the first half-dozen pages of his work the idea gradually dawned upon us that he intended it for an elaborate joke, very much after the manner, we should suppose, of Mr. Benjamin Allen and Mr. Robert Sawyer, had those gentlemen been tempted to follow the paths of literature. But, *adhibenda est in jocando moderatio*, and never more so than when the joke is at the expense of a venerable parent. In dedicating his work to his father Mr. Boddy, for the credit of human nature, must be acquitted of the charge of a conscious joke, otherwise such an instance of filial disrespect would be without parallel.

This astonishing production owes its origin to a letter advising total abstention from salt, which had appeared in a temperance journal, and the author felt himself constrained, for the good of humanity, to deliver himself of the succession of "*farcical puerilities*" and "*whimsical crudities*" which make up the "*imaginative plerophory*" "*redundant of inane folly and trivial hyperbole*" of his book. The words in italics are Mr. Boddy's; he of course applies them to the opinions of other people. With the sanction of Vespasian's law, that it is unlawful to give ill language first, but civil and lawful to return it, we think ourselves justified in applying them to Mr. Boddy's book. And how richly that book merits them we proceed to make abundantly clear, and on the author's own showing.

Mr. Boddy is too hard upon the unfortunate letter-writer in the journal of temperance: he is not even grateful to him as the remote cause of the existence of his own book. The letter-writer, "with amusing self-complacency, accused it [salt, not temperance] of producing evils of an astounding nature—such is the latitude of pragmatical ignorance and silly egotism. The palpable absurdity of such an argument must be apparent even to the most careless thinker: it is with the view of exposing such a fallacy, both injurious and irrational, that I have written this treatise." One is tempted to ask—If the argument is so palpably absurd, even to the most careless thinker, why in the world has Mr. Boddy taken the trouble to write his treatise?

It does not seem to be generally known what would happen to a world devoid of salt; such, according to Mr. Boddy, is the "dense obtenebration with which the subject is surrounded." The picture of a saltless world, as drawn by our author, is something awful to contemplate. Nothing but the thought of "our ignorant conceits," our "unaccountable obliquity of judgment," and "the apathetic indifference" with which we have hitherto looked upon the humble condiment which has graced our tables "in the smallest receptacles, as if it were the most expensive article," and to which we, "in the most finical, grotesque manner," help ourselves "in almost infinitesimal quantities, as if it were a mark of good breeding and delicacy," would compel us to reveal the "imaginative plerophory." The nervous reader will be pleased to fortify himself with at least a teaspoonful of the condiment before he begins its perusal.

"Were the human race once deprived of the chloride of sodium, even for a limited period of time, we should not only lose a natural healthful incentive for our food, but disease, with all her attendant miseries, would spread with such relentless impetuosity as would defy, and even paralyse, the efforts of the most skilful physician, the ingenuity of the surgeon, and the scientific improvements and hygienic precautions of the sanatarian. The strength and vigour of manhood would fade as if blasted by disease, food would act as a poison, the blood would not be replenished with the salt which it requires, and consequently our skins would soon be covered with corruption, our cattle would die, our crops would be nipped in the bud, the air would be full of offensive insects, the soil would become foul and barren, the sea a waste of stagnant waters, and all the beautiful productions of nature would wither and decay, and our glorious earth would degenerate into a hideous solitude, solely inhabited, very probably, by monsters horrible to behold, more repulsive than those gigantic reptiles which once roamed by the dreary marshes of an incomplete world."

And yet, according to Mr. Boddy, "the English working classes are nearly, if not altogether, unacquainted with the benefit of salt": "at the tables of the wealthy it is perfectly absurd to see the small amount which is used." We are not even allowed the poor consolation of knowing that in our false economy we are unwittingly conserving our choicest blessing. "We do not diet ourselves as we should: in this respect we are far behind the veriest

savage, cannibal though he be." We cannot inure ourselves to salt at too early an age; we ought indeed to pickle our babies: "To rub new-born infants with salt" is a practice "in every respect cleanly" and "strictly conducive to health."

Mr. Boddy has evidently spent much pains on his history: but, as he confesses, in trying to begin at the beginning he has laboured under many difficulties. He has traced the history of salt from the time of Moses and Job by the aid of such written records as he has been able to meet with, but on the question of its history before their time he is obliged to fall back on his inner consciousness.

"The origin of salt is one of those enigmas of nature which as yet has completely frustrated the most accomplished and scientific geologists, and no suggestion has yet been made which will satisfactorily and conclusively account for its formation; for whatever hypothesis has been stated there is sure to be an objection so difficult to overcome that the author has been fain to admit that it is thoroughly impracticable, and therefore inadmissible."

Even our author is fain to express himself guardedly on this point—

"If we take salt as a whole, leaving out of the question altogether the different conditions in which it is found, and with no reference at all to its existing either in the earth, above the earth, in lakes, or in the sea, but looking at it simply as it is, a mass of rock, or a volume of water holding it in solution, it inclines one to the belief that it possesses a dual inchoation, though the original source of both may have been connate; but owing to extraneous causes which were brought to bear, one branch became crystallised rock-salt, while the other, through immaturity, remains in a state of solution."

"Why the sea is salt" has given rise to many pretty fables: Mr. Boddy invents still another fable; but it is not at all pretty: it is that "sea-water is the result of some subterranean communication with reservoirs of salt through the media of volcanic foci" (p. 53). This perhaps hardly does justice to Mr. Boddy's powers of narrative: the picture of the saltless world proves that he can do better; and yet even this is surpassed by that of the insect world of Cheshire on a rainy day (p. 60). But it is scarcely fair in the interests of the book itself to quote all its best things, even if our space and the reader's patience were longer.

Mr. Boddy is apprehensive of the reviewers: "An unknown author is placed at a great disadvantage and at the mercy of those who may laud a book to the skies if they please, satirically criticise another, and pass over a third with a sarcastic smile or a significant shrug of the shoulders. I am afraid that my little volume will unfortunately be found among the latter, but I candidly acknowledge that I hope it will be regarded as belonging to the first, or at least the second."

Our theory of the origin of this book differs somewhat from that of its author, as given above; Mr. Boddy's father (to whom the book is dedicated) was, we are informed, a ship's surgeon; and it occurs to us that this book is the result of the molecular motion of a brain which can trace its ancestry to a prolonged regimen of salt junk and pickled pork. It is the most striking instance of heredity we have yet met with, and despite our fear that Mr. Boddy may describe our notion as "a brazen assertion and a subtle paralogism," we commend it to the notice of Mr. Francis Galton.

OUR BOOK SHELF

Text-Book of Practical Organic Chemistry for Elementary Students. By H. Chapman Jones. 100 pp. (London: Joseph Hughes, 1881.)

MOST teachers of organic chemistry have felt that if their students could be made to work through a fairly simple series of typical experiments the work of learning would be rendered easier, and the knowledge gained would be made more definite and more real. Just such a series of experiments is described in this little work by Mr. Chapman Jones. The experiments are well chosen and clearly described; no costly apparatus is required, yet the student who works carefully through the book will certainly have laid a solid basis of knowledge of organic chemistry on which he may build a satisfactory structure.

An outline of methods whereby organic acids may be detected is given towards the end of the book, but the main part is devoted to experiments illustrative of fractional distillation and precipitation, formations and general properties of leading hydrocarbons, alcohols, and acids, etherification, &c.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Trevandrum Observatory

As I was reading in a recent issue of your valuable journal (vol. xxiii. p. 482) a letter on the magnetic storm of August, 1880, showing the universality and simultaneity of the disturbance by comparing the observations at Greenwich, Toronto, Zi-ka-Wei, and Melbourne, I felt curious to know whether any such disturbance was noted here in the Government Observatory, and if so, whether the time corresponded with that given in your paper. On my application the gentleman in charge of the Observatory put into my hands, the inclosed abstract for the whole month of August, which I herewith forward to you. It contains, as you will see, not only the magnetic observations with the unifilar, bifilar and balance, but also the meteorological data for the necessary correction, &c. The reference throughout the paper is to the local time, which may be easily reduced to the Greenwich time, as the longitude is given. The observations, I may add, are quite reliable, though made by native agency, and I hope may prove useful on this occasion. But the paper inclosed I fear is too long to find room in your crowded columns, and what I beg you to do is to place it at the disposal of any of your scientific contributors or friends who take an interest in the question of terrestrial magnetism, and may be therefore expected to make use of the material here furnished.

A word more before I close. Your readers might know this observatory, said to be situated near the magnetic equator, was once in a very flourishing condition under the direction of Mr. John Allan Broun. On his retirement to Europe the establishment was reduced and a limited series of observations introduced, which he continued to direct till his recent demise. Since then the observations recorded are lying unused for the want of a scientific chief. If any scientific gentleman or society should generously offer some help in the way of directing the labours of this institution, I venture to think that the Government would gladly avail itself of such help, and the cause of science could then be materially promoted. Symbolical Logic

FRESH criticism of my logical writings in a work just published ("Symbolic Logic," by John Venn, M.A., Fellow and Lecturer in the Moral Sciences, Gonville and Caius College, Cambridge) must be my excuse for troubling the editor and readers of NATURE with a third letter on the above subject.

On page 94 of his work Mr. Venn strikes the key-note, as it seems to me, of its whole purport and spirit. "Those who propose a new notation," he says, "commonly, and not unnaturally, assume that it is to supersede all others. But those who approach it as strangers know that the odds are decidedly that it will only prove one more of those many attempts which perplex and annoy the lecturer, historian, and critic. Hence we may fairly use the argument, dear to those in authority, that if we loosen the sanctions of orthodoxy, heresies will multiply. Only those whose professional employment compels them to study a number of different works have any idea of the bewildering variety of notation which is already before the world. . . . No doubt it would be rank intolerance to forbid such new attempts, *but an attitude of slight social repression towards them may serve to check too luxuriant a growth of new proposals.*"

The italics are mine. Alas, how little Mr. Venn appreciates the irrepressible restlessness of that most ungovernable organ, the human brain, if he really thinks that the "attitude of slight social repression" which he recommends would have the desired effect! Amateur logicians, as well as professionals, *will* start theories and invent notations of their own in happy unconsciousness that they are causing any annoyance to "lecturers, historians, and critics," whom indeed they not improbably picture to themselves (when the all-absorbing nature of their occupation allows them to think of them at all), as ardent devotees of science like themselves, who will be delighted with the new instrument of research which they hope to place in their hands. And more provoking still, scientific societies and editors (including a goodly number of the said lecturers, historians, and critics) *will* print in their *Proceedings* and magazines new proposals which they think likely to prove interesting or valuable, without being influenced by any motive whatever beyond a pure and simple desire to further the progress of science.

Mr. Venn professes great admiration for the late Prof. Boole's genius, and I heartily agree with him, though we admire on somewhat different grounds. I ground my admiration on the fact that Boole worked wonders with an unnecessarily complicated and otherwise defective symbolical method of his own invention. Mr. Venn apparently grounds his admiration on the singular supposition that Boole's method is really very simple and very effective, but that its author did not understand very clearly the real principles of its construction, and did not by any means apply it with as much ease and dexterity as he might have done. I am quite sure that this is not the impression which Mr. Venn intended to create in the minds of his readers, but I am no less sure that this is the impression which a perusal of his book *will* create in their minds—at least in the minds of such as have not read Boole himself. One remark of Mr. Venn's surprises me. He says (p. 385) that Boole "justly regarded his problems in Probability as the crowning triumph of his system." Surely I am not mistaken in my impression that I have somewhere seen Mr. Venn quoted as holding an opinion very much at variance with this statement—in fact attacking as erroneous the very principle on which Boole's "General Method in Probabilities" is based. May I ask Mr. Venn this plain question, Does he or does he not agree with Boole's solution of the question which he proposed on pp. 321 and 336 of his "Laws of Thought" as a decisive "test of the sufficiency of received methods," and (by implication) of the efficacy of his own General Method?

The main points on which Mr. Venn and I differ are the following:—

1. Mr. Venn maintains that the sign + in such expressions as $x + y + z$ should in logic, as in ordinary algebra, be always understood in an *exclusive* sense, so that unless we know x, y, z to be mutually exclusive, the above expression should be written in a different and, as he admits, a much less simple form. I hold, on the contrary, in common with Prof. Jevons and several others, that since, on the non-exclusive plan, the simple form $x + y + z$ may, without the slightest risk of ambiguity, be substituted at any stage of an investigation for any of its exclusive equivalents (such as $x + x'y + x'y'z$), or be replaced, if necessary, by any exclusive equivalent, the non exclusive interpretation of the symbol + gives us far more mastery over our symbolical expressions, and should therefore be preferred to the needlessly restrictive and hampering exclusive interpretation which Boole attaches to this symbol. How very serious the disadvantages of this interpretation really are is unwittingly illustrated by Mr. Venn himself on p. 262, where he finds himself obliged to admit that certain important simplifications which he discusses are "purely a matter of tact and skill, for which no strict rules can be given." If he had read my third paper in the *Proceedings* of the London Mathematical Society a little more attentively he would have found in my directions for reducing any complex disjunctive expression to its "primitive form" that these simplifications are not at all a pure matter of tact and skill, but may be obtained by a simple, never-failing, and purely mechanical process, which, however, a little tact and skill may do much to abbreviate. On the exclusive interpretation of the symbol + this process would be simply unmeaning. The problem which Mr. Venn discusses (expressed in my notation) is this:

Reduce the expression $(f:g)\ (gl:f)\ (l:f')$ to its simplest form.

By inspection [since any implication $\alpha:\beta$ is equivalent to $\alpha\beta':0$, and any compound implication of the form $(\alpha:x)\ (\beta:x)\ (\gamma:x)$ to a single implication $\alpha+\beta+\gamma:x$] this, on the non-exclusive plan, is seen to be equivalent to $fg' + glf' + lf:0$.

Reducing the disjunctive antecedent of this implication to its *primitive form* (a purely mechanical process, as already remarked), we get $fg' + gl:0$, or its equivalent, the compound implication $(f:g)\ (g:l')$, a result which Mr. Venn obtains apparently by a vague tentative process "for which no strict rules can be given."

2. Mr. Venn and I also hold different opinions as to whether or not symbolical logic should have signs to express relations corresponding to those of subtraction and division in mathematics. His opinion is that such signs *should* be introduced, and at once. My opinion (an opinion which I believe I share with most logicians) is that we had better not encumber ourselves with those symbols till they can be proved to subserve some useful purpose. The important question is—not, as Mr. Venn appears to think, whether such symbols can be intelligibly interpreted, but whether they will in any way help us in discovering new truths; in other words, whether they can be turned to any practical use in the solution of logical problems. If Mr. Venn can adduce a single intelligible logical problem which can be solved more simply or easily by the help of these signs than without them, I shall declare myself at once a convert to his views. So far I have come across no such problem, and must therefore for the present remain in the ranks of his opponents. As an illustration of what Mr. Venn calls the inverse method (*i.e.* division) in logic, he gives (p. 266) the equation—

$$(x + \bar{x}y)\ w = x + \bar{x}yz,$$

in which w (which denotes the books *in a certain library*) is to be expressed in terms of x, y, z (which respectively denote *philosophical* books, *divinity* books, and *protestant* books). His result is—

$$w = x + \bar{x}yz + \frac{0}{0}\bar{x}\bar{y},$$

which he translates into ordinary language thus:—

"The library must have certainly contained all philosophy and protestant divinity, and may possibly have contained any kind of works which are neither philosophy nor divinity; this latter constituent being left entirely indefinite."

Mr. Venn's data in the non-exclusive notation would be—

$$(x + y)\ w = x + yz,$$

and my result (much more simply and easily obtained) is—

$$w : x : : \bar{x} : y + y' .$$

According to my definitions of my letter-symbols, we speak throughout of some *one* originally unclassed book, so that w, x, y, z will respectively denote the statements: It is in the *library*; It is a *philosophical* work; It treats of *divinity*; It is a *protestant* work. My result may therefore be read:—

Any work on philosophy or protestant divinity will be found in the library; and every work in the library is either philosophical, secular, or protestant. (By a *secular* work I mean simply a work that does *not* treat of divinity.)

The antecedent of w in my result is equivalent to the first "constituent" in Mr. Venn's result; but the consequent seems to me to give us much more intelligible information about the library than Mr. Venn's latter constituent ("May possibly have contained," &c.), which he truly describes as "entirely indefinite."

3. Another opinion of Mr. Venn's, unless I misunderstand him, is that all logical equations should, as a preliminary to their solution, be expressed in the form $\alpha = 0$, which, of course, is equivalent to my $\alpha : 0$. My opinion is that this, in logic as in mathematics, is sometimes convenient and sometimes not, and that we should not in logic, any more than in mathematics, tie our hands by this or any other unnecessary restriction.

The other points in which I differ from Mr. Venn have been mentioned in my former letters (see NATURE, vol. xxiii. p. 578, and vol. xxiv. p. 5), and need not be here repeated. Mr. Venn however labours under a serious misapprehension if he thinks that I attach any importance to the distinguishing features of my method *as mere barren conceptions*. Their real importance lies in the *use* which I have made of them, and this use cannot be fairly appreciated without examination of my published solutions in the *Proceedings* of the London Mathematical Society, in the *Educational Times*, and in the *Philosophical Magazine*. I must protest against that spirit of criticism which would offer two or three chipped bricks as a fair specimen of a house, and would depreciate the labours and damp the zeal of all scientific workers by unduly emphasising the undeniable fact that all logical and mathematical methods are, after all, mere combinations, developments, or extensions of a few simple truths which are the common property of all mankind. Even Boole's "actual originality," Mr. Venn tells us, though I think he means *priority*, "was by no means so complete as is commonly supposed and asserted" (see Mr. Venn's Introduction, p. 28). According to this method of criticism we might ascribe the invention of the steam-engine to the person (unfortunately unknown) who first discovered the important principle of a revolving wheel, and turned it to practical account by making a wheel-barrow.

In conclusion I must thank Mr. Venn for the compliment which he kindly pays me on p. 372 of his work, but I think it would read better without the parenthesis, "as he assures us is the case." The "assures" is a little too strong for the simple statements which I made, and which it never occurred to me that any one would dream of doubting. The compliment would also please me more if it did not so completely ignore the earliest, the most difficult, and the most important of my papers in the *Proceedings* of the Mathematical Society, namely, that which treats of the limits of multiple integrals. This part of my method (which gave rise to all the succeeding developments) resembles nothing, so far as I know, that has preceded it; and if Mr. Venn had found time to read it, the objectionable parenthesis which I have quoted would scarcely have presented itself to his mind as in any way called for. HUGH MCCOLL

Boulogne, May 25

Resonance of the Mouth-Cavity

SINCE communicating to Mr. Sedley Taylor my recent observations on the capabilities of the mouth as a resonator, and forwarded to you, with my permission, for publication in NATURE, I have made the following experiments with perfect success, and believing that they will be interesting to your acoustical readers I send a list of them to you, and hope you will be able to find a place for its insertion in your next issue:—

Experiment I.—While one of the overtones of a loud prime was resounding in my mouth another person heard it distinctly, upon the ear of the latter being held near the source of resonance.

Experiment II.—While a cart—any other noisy vehicle will do as well—was going along the street, I readily tested the composite nature of the noise by the resonant capabilities of my mouth.

Experiment III.—I turned the water-tap on into a basin (the water was running with a good force), and from the noise make by the falling liquid I was able to get different sounds quite easily.

In both these latter experiments I observed, while opening and closing my mouth, that the pitch rose and fell as when one slides a finger up and down a vibrating fiddle-string.

Experiment IV.—I held down in the treble part of a harmonium—with an 8-feet stop out—several consecutive keys together, and while the notes were sounding which composed the horrible discord, I was able to single out any of them separately by the sympathetic resonance of my mouth.

This experiment can be done equally well at the organ.

Experiment V.—I held down four or five of the low keys of the organ with the 8-feet trumpet drawn, and the beats of the overtones resounded very prominently, so that by taking two contiguous ones at a time the result was like the *voix céleste* stop.

Experiment VI.—I tried several notes in the c—c octave of the clarinet organ stop, and heard the regular order of partial tones by resonance, but the even ones were weak and odd ones very strong.

Experiment VII.—I held down c' and g' on the harmonium, and heard the first coincident partials beat distinctly—due to equal temperament.

Experiment VIII.—The first five partial tones of an average bass voice were studied. The notes chosen for observation were $d\flat$, f, g, $a\flat$, $b\flat$. To each note the vowels *A* as in *hay*, *A* as in *ah*, *E* as in *me*, *I* as in *high*, *O* as in *oh*, *U* as in *you*, were sung.

It was found that not only did the different vowels give different qualities, but that the same vowel had a different quality for almost every one of the five notes sung. The *E* as in *me* and *U* as in *you* had generally weak low overtones. The *I* as in *high*, on the contrary, gave them out well.

It will perhaps be as well to say, for the benefit of those who may not have tried to get a sympathetic resonance of the mouth, that success is likely to be sooner obtained by first practising the mouth in going from the *ou* to the *ah* shape, and from the *ou* to the *e* shape.

It is also recommended that the ears be stopped by the fingers when doing these experiments, in order to lessen the possibility of mistaking the direct sound for resonance.

JOHN NAYLOR

5, West Park Terrace, Scarborough, June 1

"How to Prevent Drowning"

I FEAR that if persons who cannot swim place reliance on the advice given by Mr. MacCormac in your impression of June 2 (vol. xxiv. pp. 62, 101) they will hardly succeed in saving their lives should they happen to fall into deep water. It is an error to say that the "human frame, bulk for bulk, is lighter than water," for unless that frame be covered with fat beyond the average, it has a greater specific gravity than water. And after all, a tolerably fat body is lighter, bulk for bulk, than water only by virtue of the air in its lungs, and should that air be expelled by the frantic screams of the immersed person, he will soon find, if unable to swim, that the notion of his frame being specifically lighter than the water is a myth. The dead body even of a tolerably fat person being destitute of air in the lungs, sinks at once to the bottom in salt as in fresh water. The average human being, were he to permit his body to sink as far as it will, would soon find himself at the bottom of the sea or river. Besides, even in the case of a person fat enough to be lighter, bulk for bulk, than water, it is necessary that he should assume a certain position in order that he may succeed in keeping his nose and mouth above the water, and unless he learn how to do this in the water itself I doubt if instruction on dry land would ever enable him to float. We all know the story of the Hibernian who, having narrowly escaped drowning, vowed he would never enter the water again until he had learnt to swim, but we are not told if he ever qualified himself for going into the water again. To try and persuade people that by attending to certain rules they may get into deep water without the risk of drowning is to create a false confidence which will rather increase than diminish the number of deaths by drowning. Imagine a terrified person just plunged for the first time into deep water trying to recall all the directions he has read about shutting his lips, swallowing his breath, permitting his body to sink until it shall displace as much water as equals the body's weight, treading the water, and so on. Why he would require, in the midst of his agony of fear, to possess as many contradictory qualities of mind as Macbeth says no man can have. I venture to assert that no one was ever saved from drowning by following such directions as your correspondents here give. It should be stated in the plainest manner that there is no safety for a person in deep water but in a knowledge of swimming. Swimming should be taught to every boy and girl as a necessary branch of education. It has these advantages over much that is taught in schools, that it is a useful, a delightful, and a healthful accomplishment. R. E. DUDGEON

Dust-winds at Hankow

DURING the spring of 1878 my attention was directed to the dust-winds which are not of unfrequent occurrence along the valley of the Yang-tse in the warm and dry seasons of the year. These dust-winds, as I observed them at Hankow, had sometimes the appearance of a dense mist; whilst at other times the air seemed to be penetrated by a fine haze; and in all cases a fine and almost impalpable dust was deposited

which was with difficulty excluded from the interior of houses. Their duration varied from a few hours to two days; and from the fact that one of the dust-winds was simultaneously experienced at Hankow, Kiukiang, and Chinkiang—a portion of the river's course nearly equal to 450 miles—I may conclude that they were not local phenomena, but possessed a considerable horizontal extension. The dust, which in all respects resembles the loam forming the banks and alluvial plains of the Yang-tse, is composed of mineral particles and vegetable *débris*—the former varying from $\frac{1}{500}$ to $\frac{1}{1000}$ of an inch in size, and being generally siliceous or calcareous in composition.

Three dust-winds came under my observation on March 25, April 21, and May 1; all of them possessed the following meteorological conditions:—During the two or three preceding days the barometer fell, whilst the mean daily temperature rose, and in two instances the winds were light and southerly. During the continuance of the dust-winds the barometer rose, the mean daily temperature ceased to rise, and light winds with a force of 1 and 2 prevailed varying in direction from north to north-east. For a period of a day or two after the dust-winds had ceased the thermometer registered a lower mean daily temperature, the barometer continued to rise, and the wind retained the same northerly direction. In all three cases there was a disturbed electrical condition of the atmosphere: in the first instance a severe thunderstorm accompanied by heavy rain occurred on the day following; the second dust wind was accompanied at its commencement by a little thunder and lightning, but by no rain; whilst during the two days preceding the third dust-wind there was a considerable amount of thunder and lightning, together with heavy rain.

From this comparison of the prevailing atmospheric conditions in connection with these dust-winds, a more probable explanation of their occurrence may be obtained, than that which is often proposed when simply assigning a "sudden breeze" and a "hot day" as the conditions required to give rise to them.

A Singular Cause of Shipwreck

THE strange loss of the *Phœnix* off the Iceland coast may perhaps lend some interest to the following:—

Last summer was the best the Icelanders had had for long past. I regret that I can give no thermometric readings, as my instrument became useless during the voyage. The weather in the north was nearly as warm as it has been here lately. All the snow-fed rivers were very full. The Jökul-á was nearly up to its high water-mark quite early in the season, and the Blanda was almost impassable. Icelanders who rode with me said that they had never seen the mountains from Hoffs Jökul to Eyrik's Jökul so free from snow.

I append extracts from a letter which I have just received from one of my guides.

A. J. HUBBARD

St. Thomas's Hospital, S.E., June 4

(*Verbatim copy*)

"Hjedinstrofda, April 16, 1881

". . . This winter has been so uncommonly strong that none such has existed this century. The frost has been extremely severe—32° R., once at Akureyri, and 36° R. (= 49½° Fahr.) somewhere with Myvatu. . . . Ptarmigans and other birds froze to death. The farmers had spent most of their hay, and their cattle were to be killed or starve to death. All the sea was covered with ice, mostly polar ice, as far as one could see from the tops of the mountains. On the 2nd inst. the weather was mild, and on the 7th we had a real thaw, and every day since very mild and fine weather. But —— it is possible that the ice will not drive away before late in August, and no ship can come to any harbour on the northern coast; this happened (also in) 1869. "KRISTJÀN JÓNASARSON"

An Optical Illusion

THE optical illusion described in NATURE, vol. xxiv. p. 54, is, as I have already mentioned, referred to by Priestley (History, &c., Vision, Light, and Colours, vol. ii. p. 725). The description is as follows:—"M. Le Cat well explains a remarkable deception by which a person shall imagine an object to be on the opposite side of a board when it is not so, and also inverted and magnified. It is illustrated by Fig. 162, in which D represents the eye and C B a large black board pierced with a small hole. E is a large white board placed beyond it, and strongly illuminated, and *d* a pin or other small object held betwixt the eye and the first board. In these circumstances the pin shall be imagined to be at F on the other side of the board, where it will appear inverted and magnified, because what is in fact perceived is the shadow of the pin upon the retina; and the light that is stopped by the upper part of the pin, coming from the lower part of the enlightened board, and that which is stopped by the lower part coming from the upper part of the board, the shadow must necessarily be inverted with respect to the object." ("Traité des Sens," par M. Le Cat, Amsterdam, 1744, p. 298.)

Birmingham and Midland Institute, Birmingham, June 6

THE VISITATION OF THE ROYAL OBSERVATORY

THE Report of the Astronomer-Royal to the Board of Visitors on Saturday last at the annual visitation was listened to with special interest, and indeed the attendance of astronomers and others at the Observatory was very much larger than usual, because it was generally understood that this would be the last occasion of the kind on which the veteran astronomer would be seen at his post. We learn that an appropriate address was made to him by the Board of Visitors when he announced his attention of relinquishing his official duties in order to enable him to devote all his time and energies to the researches he has now on hand.

The astronomical observations, which occupy the first part of the Report, have been carried on with the usual diligence. Most of the routine work of the Observatory seems to have gone on in the usual fashion through the last year.

One of the objects of interest on this occasion was Halley's ancient tombstone, which, after its removal from Lee Churchyard (where it had been replaced by a new stone with a facsimile of the inscription), had been placed in the South Ground, where it had been lying for several years. It has now been carefully restored, and mounted on the east wall of the lobby of the North Dome.

The sun's chromosphere has been examined with the half-prism spectroscope on 29 days during the period to which this report refers. Fourteen sun-spots have been examined on 20 days, with reference to the broadening of the lines in their spectra. The results confirm the remark that some of the lines of iron are broadened in some spots, whilst others are broadened in other spots. Displacements of some of the lines of iron towards the red, and of others towards the blue, have also been noted in the case of one spot. A remarkable spectrum of a sun-spot showing 17 strong black lines or bands, each as broad as b_1, in the solar spectrum, was observed on November 27 and 29, 1880. These bands, to which there is nothing corresponding in the solar spectrum (except some very faint lines), have also been subsequently remarked in the spectra of several spots.

For the determination of motions of stars in the line of sight, 168 measures have been made of the displacement of the F line in the spectra of 43 stars, 87 of the b_1 line in 27 stars, and 8 of the b_4 line in 4 of these stars. Of these 70 stars 16 had not previously been examined, and the total number of stars of which the motions have been spectroscopically determined is now 91. In the case of 6 of the stars observed in the last year, a dispersive power equivalent to that given by 16 prisms of 60° has been used. Ten measures have been made of the relative displacement of the F and *b* lines in the spectra of the east and west limbs of Jupiter.

Comet 1810 *d* (Hartwig's), and the aurora of 1881, January 31, have been spectroscopically examined.

Between 1880, May 9, and 1881, May 13, photographs of the sun were taken on 140 days, and of these 284 have been selected for preservation. There are only 8 days

out of 149 days on which the sun's disk was observed to be free from spots, whilst in the preceding year there was a complete absence of spots on 64 days out of 145.

The spectroscopic observations of all kinds have been completely reduced to 1881, May 6.

Touching the magnetical and meteorological instruments it was pointed out that the alterations of the photographic cylinders of the magnetical and meteorological instruments, which were in contemplation at the time of the last report, so as to make their time-scales the same in extent and in position on the record-sheets, have been to a great extent carried out. In the case of the declination and horizontal force magnets, two reflecting prisms with convex cylindrical front surfaces have been mounted by Mr. Simms above the registering cylinder, which has been lowered so that each prism receives the light from the magnet opposite to it. By this arrangement the traces of both magnets fall (as regards time-scale) on the same part of the sheet. The cylindrical lenses formerly used have been removed, being replaced by the cylindrical surface of the prism. The new arrangement is found to be perfectly satisfactory, and Mr. Simms is proceeding with a similar change in the case of the earth-current apparatus and of the vertical force and barometer registers.

A modification has been made in the system of determining the time-scales by the substitution of hourly breaks in the register, for the photographed hour-lines. The break at each hour is made automatically by a slight alteration in the apparatus hitherto used for registering the hour-lines. The time-scales for the declination, horizontal force, vertical force, barometer, and electrometer are now laid down in this way.

The unsatisfactory state of the earth-current register has been already noticed. After the change mentioned in a preceding section, it was soon found that the indications of the earth-current wires were disturbed by a continual series of petty fluctuations which almost completely masked the proper features of earth-currents. By cutting off the communications with those parts of the wires called the North Kent East Line and the Ladywell Line these disturbances were checked; but there remains a periodical disturbance at every hour, which entirely destroys the value and credit of the results. It seems not impossible that something may depend on imperfection of earth-communication. If this fault cannot be removed, the Astronomer-Royal proposes to return to the original system of independent wires (formerly to Croydon and Dartford).

The new pressure plate of Osler's anemometer has worked well. The limiting pressure of fifty pounds on the square foot was twice exceeded during the snow-storm of 1881, January 18.

The photographic records of the measures of magnetic earth-currents, in two directions upon the earth's surface nearly at right angles to each other, are maintained with the same regularity as those of the ordinary magnetic forces, and are preserved in readiness for reference or publication when need may require. An extensive confederacy is now organised, principally in Germany, for register of the earth-currents at several stations.

The following are the principal results for magnetic elements in the year 1880:—

Approximate mean westerly declination ... ... 18° 32′

Mean horizontal force ... ... { 3·912 (in English units). 1·804 (in metric units).

Mean dip ... ... { 67° 34′ 55″ (by 9 inch needles). 67 35 53 (by 6-inch needles). 67 36 3 (by 3-inch needles).

The report proceeds:—

"In respect of diurnal inequalities of magnetic horizontal force and its direction, though all measures are ready, the curves are not yet actually formed. In the last report I adverted to the usual character of these curves. Assuming it to be certain that they originate from the sun's power, not immediately, but mediately through his action on the earth, it appears to me (as I suggested long ago) that they are the effects of the attraction of the red end or north end of the needle by the heated portions of our globe, especially by the heated sea, whose effect appears to predominate greatly over that of the land. I do not say that everything is thus made perfectly clear, but I think that the leading phenomena may be thus explained. And this is almost necessarily the way of beginning a science."

The number of hours of bright sunshine, recorded with Campbell's Sunshine Instrument, during 1880, was 1214, which is about the same as the average of the four years for which we have a record.

The discussion of the electrometer results for the year 1879 shows that the potential of the atmosphere is usually positive; that it is least in summer and greatest in winter, and especially in the colder weather of winter. There is also a definite diurnal inequality, having double maxima and minima, the maxima, on the average of the year, occurring at about 8h. a.m. and p.m. and the minima at about 3h. a.m. and p.m. In character the diurnal curve has a resemblance to the barometric curve, but the points of maxima and minima precede those of the barometric curve by about two hours. On days of magnetic disturbance, when aurora is visible, nothing unusual is remarked in the electrometer indications. Excepting thunderstorms the greatest disturbances are experienced in showery weather, and are probably local disturbances only.

The time work is thus referred to:—

"In the first few years after the strict and systematic examination of competitive chronometers, beginning with 1856, the accuracy of chrono neters was greatly increased. For many years past it has been nearly stationary. I interpret this as showing that the effects of bad workmanship are almost eliminated, and that future improvement must be sought in change of some points of construction. One which occurs to me (I mention it principally as a specimen of departure from customary forms) is this. The impact of the escape-wheel upon the pallet of the balance-axis takes place very near to that axis, and must produce considerable friction, though of short duration. I proposed to the late Mr. Charles Frodsham to meet this by use of a broader pallet and a lighter impact of longer duration. The decease of that accomplished horologist prevented the completion of the trials which he had commenced for carrying out my suggestion. Other variations of the established form might be worthy of trial.

"The Greenwich time-ball has been regularly dropped automatically at 1h. on every day throughout the year, with the exception of 6 days when the violence of the wind made it imprudent to raise the ball, and 8 days when the severe frost of last winter prevented its being raised; and of one day when there was accidental failure.

"The Deal ball was not raised (on account of high wind) on 10 days. It was not dropped (through failure in the telegraphic connection) on 7 days, and was erroneously dropped about 5s. too soon by telegraph signals on one day; and on another day it was not dropped at 1h. owing to telegraph signals continuing up to 1h.; on one day the current was too weak to release the trigger. On every other day the ball has been dropped automatically at 1h.

"As regards the Westminster clock, its errors have been under 1s. on 31 per cent. of the days of observation, between 1s. and 2s. on 47 per cent., between 2s. and 3s. on 18 per cent., and between 3s. and 4s. on 4 per cent.

"The distribution of time-signals to all parts of the country continues to be made on the same system as in late years, by means of the chronopher at the central

office of the Post Office telegraphs. In connection with this system, I would express the hope that the proposal to establish an hourly signal at the Start Point will be borne in mind.

"Last autumn a telegraphic determination of the longitude of Leiden was made with great care by M. M. Bakhuyzen. The interchange of signals between Greenwich and Leiden occupied nearly four months. I may here remark that the American extension of longitude carried out under Commander Green, U.S.N., to which reference was made in the last report, will be most useful for the transit of Venus in 1882. Cannot a British officer be found to complete the operations for Australia and New Zealand? I lament that this has not been done. Mr. Gill has undertaken the necessary work for the Cape."

The following important general remarks conclude the report:—

"The present meeting may afford a fitting opportunity for the expression of my views on the general objects of the Observatory, and on the duties which they impose on all who are actively concerned in its conduct. Assuming as beyond dispute that these ought to be carried out in a spirit liberal in itself and honourable to the nation, I proceed to state my opinion on the line of action which they suggest.

"The object prescribed to the Observatory is the promotion of "Astronomy and Navigation." And, since the abolition of the Board of Longitude, the second of these objects (which historically gave rise to the introduction of the first) presses upon the directors of the Observatory much more strongly than before. Considering then the claims of astronomy as b aring on navigation and our responsibilities in reference to them, we find that those responsibilities are by no means narrow. Whatever the rest of the scientific world may do or may not do, we are responsible for determinations of the fundamental elements of sidereal, solar, and especially lunar astronomy, with the highest accuracy that modern skill can secure. The same apparatus of instruments and of mathematical treatment which fix the places of fundamental stars will apply to those of other stars; the same which apply to the sun will apply to planets and comets (not unconnected with solar theory, by virtue of perturbation) and even to satellites. And we could hardly consider ourselves as discharging our duty to the more educated portion of the nation, or as maintaining our proper position in the world, if we did not include in our operations these latter offshoots of the first-mentioned objects.

"But new astronomical subjects have arisen of which no one dreamed when our constitution was first fixed. The first of these was the measures of double stars. But this, though important as ever, has almost disappeared from our view when occupied with solar and spectroscopic physics. I yield to no one in the interest which I take in these subjects, and in the admiration with which I regard the positive conclusions and the problematic suggestions which are founded on them. But I still point out that these are not parts of our original system, and their connection with the Greenwich Observatory is at any time liable to question.

"I now advert to the general subject of navigation. And first I remark that magnetism, in its ordinary and nautical form, is indisputably a proper subject for the Observatory. But within the present century there have arisen:—the accurate examination of magnetic irregularities, the partial reduction of daily irregularities to practical laws (still wanting theoretical explanation), and the establishment of the simultaneous co-existence of occasional disturbances covering the whole surface of the earth. Connected with these is the observation of magnetic currents through the terrestrial soil, registered at Greenwich for many years past, and now attracting attention on the Continent. Perhaps no branch of physics bears the same prospective importance as these. Yet I conceive that their continued study in this Observatory requires special authorisation.

"The original views in making astronomy contributory to navigation were limited to observations of the moon. But in the latter part of the last century the possibility of making chronometers subservient to the determination of longitude (a subject to which the late Board of Longitude gave good attention, and to which the Government has always offered liberal rewards) was proved, and in the present century the improvement has been very great. This has been effected by our Hydrographical Office (mainly through the action of the Observatory), partly by specific rewards, partly by careful attention to the accuracy of every chronometer purchased. And the practical value of the chronometric system has been very greatly increased by taking advantage of the galvanic distribution of time currents, and by the galvanic exhibition of ball-drops and other signals. There can be no doubt that all the agencies involved in this system are well employed, and that they are a legitimate part of the Observatory duty as originally contemplated.

"Still I remark that the Observatory operations bearing on chronometric navigation are not carried out to the extent which I could desire. It is known to all persons familiar with chronometers that rates of the chronometers, obtained while the ships are actually in voyage, would possess remarkable value. We possess the power of giving facility for obtaining these to a large part of our mercantile navy, by exhibiting a time-signal at every hour, at Deal (where the necessary apparatus already exists) and on the Start Point. I have several times brought this proposal, as regards the Start, before the Government, but unsuccessfully. But I should have done wrong if I had omitted, in this general survey of the duties of the Observatory, to state my continued conviction that this is a proper and very desirable addition to the other points of assistance which we can give to navigation.

"Next—closely connected however with the subject of navigation—is the knowledge of the longitudes of distant ports, as referred to the Greenwich Observatory. And I approach this subject with grief. We have entirely abandoned the longitudes of the Atlantic, which have been cleared away, before our eyes, by the scientific enterprise of another nation. The Pacific, bearing those vast and important colonies, almost entirely British, is equally neglected; though so much is ready that the mission of a single officer would quickly establish all. The same aspiring nation which has mastered the Atlantic is now bent (as I understand) on adding to its scientific dominion the Pacific. I think this is not honourable to our nation.

"There remains another subject, which occupies no small part of the force of the Observatory, and which I am unable to connect with either of the two great divisions to which I have alluded—the subject of meteorology. It is exceedingly popular in the country, perhaps because it requires little of expense or of science. It is also pursued at many foreign observatories, where vast numbers of observations are produced without attempt at classification or reduction. We at least are not amenable to this accusation, and may appeal to our reduction of more than twenty years' collected observations as giving matter of permanent interest to the more scientific meteorologist, and even to the geologist. Still I call attention to the fact that this is a subject which, though introduced mainly by myself, I regard as foreign to the original 'Astronomy and Navigation' of the Observatory.

"There is still a matter for consideration, not in our observations, but in the mechanism by which they are made available to the world—I mean our printing. I have repeatedly expressed my opinion that the extent of our printing is far too great: not in the full exhibition of reductions, but in the minute details of individual observations. There are printed every year more than 7000 transits or circle readings, each consisting of 6 or 7 indi-

vidual readings, of which only the mean is useful. I do not believe that, since the year 1835 at least, any person in the world except ourselves has actually taken a mean. As each reading contains 3 or 4 figures, there are printed in each year something like 150,000 useless figures. Reliance must be placed somewhere on the skill and fidelity of the observer, and (considering the severity with which every figure of transit-wire and of circle microscope, and of their means, is examined here) this reliance may be placed at least as well on the means as on the originals. I have reason to think that the bulky volume of nearly 900 pages, might be reduced to about three-fifths of its present size by omitting those originals.

"I would submit for the consideration of the Board whether it might not be advantageous that they should hold a special meeting to consider the subjects which I have indicated. The length of time at an ordinary visitation, and the circumstances under which the Board meets, are not sufficiently favourable for the discussion of broad questions of Observatory policy."

HOLTZ'S ELECTRICAL SHADOWS

IN an extremely elegant series of researches Prof. W. Holtz of Berlin has lately brought to light the existence of a new class of electrical phenomena, to which their distinguished discoverer has assigned the name of *Electric Shadow-figures*. Though nearly six months have elapsed since they were described in the Proceedings of the Göttingen *Gesellschaft der Wissenschaften*, no detailed account of them has appeared in any English journal. Yet the shadow-figures are remarkably easy to produce, and the whole research is of extreme simplicity, as very little apparatus is required beyond the simplest odds and ends to be found in every physical laboratory, the only large instrument necessary being one of Holtz's electrical machines.

The fundamental arrangement is that shown in Fig. 1. From the discharging-rods of a Holtz machine the brass balls are removed. To the left rod there is attached in place of the ball a circular disk of some 10 to 20 centimetres diameter, having its front face either flat or slightly concave. To the right rod a point is fixed, and it is drawn back till from 6 to 15 centimetres distant from the disk. A piece of silk or satin of the same size as the front surface of the disk is laid upon it while the machine is in action, it adheres of itself to the surface, and the preparation is now complete. Before the silk is placed over the disk a small "brush" discharge of blueish light is all that can be distinguished at the point of the right-hand discharging-rod: but this now changes to a very faintly glowing star. At the same moment the central region of the silk-covered disk exhibits a peculiar glimmering light over a well-defined circle. The utmost care is needed to shut out all extraneous light from the room, otherwise the delicate appearances which follow cannot be seen. It is upon this circular patch of feeble light that the shadow-figures are thrown. Its pale gleam becomes more vivid when the machine is more energetically worked: it enlarges in area but diminishes in brightness as the point is drawn back from it, and contracts with an accompanying increase in brightness as the point is brought nearer. It is possible to obtain a similar glimmering surface also upon a large metal ball covered with silk and attached to the rod in place of the concave disk, or instead a screen made of two or three folds of silk stretched over an ebonite ring may be placed between the two discharging-rods, the ends of both being furnished with points. In each case it is important that the silk be without crease or wrinkle, otherwise an evenly illuminated disk of light will not be obtained.

If now a body of definite outline of form be interposed between the point and the disk, an electrical shadow of it will be cast upon the luminous circle. These shadows are truly electrical, not optical, for all bodies do not cast them, and, more curious still, different bodies though of the same shape may cast differently shaped shadows. Conductors of electricity cast well-defined shadows, and so do semi-conductors, such as wood and cardboard. True insulators of small dimensions cast no shadows. The insulation or non-insulation of the conducting bodies makes no difference in their shadow-giving power. A cross cut out of cardboard casts (as in Fig. 1) a well-defined shadow at the centre of the field, but the exterior portions are somewhat hazy. An ebonite cross casts no shadow. A cross made up of two strips, one of cardboard, the

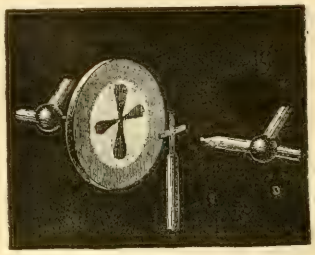

FIG. 1.—Electric shadow cast by a cardboard cross.

other of ebonite, fastened with shellac, casts only a single bar of shadow. Rings of tinfoil, cardboard, or wire also cast shadows. Such small objects are conveniently held by attaching them to the end of glass rods. The size of the shadows increases if the objects are displaced from their central position to right or left. A strip of card or thin metal casts the same shadow whether it be held broadside or edgeways in the field. A wire grating having 5 millimetres width between the bars obscures the field like an opaque body. Breathing on a strip of ebonite or glass renders its surface a feeble conductor, and it casts a transient shadow. A glass rod heated at one point casts a shadow at the heated point, the shadow dying out as the

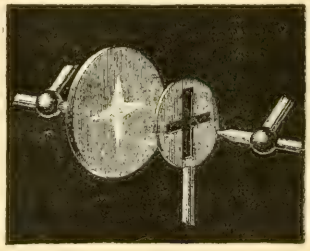

FIG. 2.— uminous figure projected through aperture in cardboard screen.

rod cools. No shadow is cast by a conductor whose surface is completely covered by insulating material, such as a shellac-covered wire or a glass tube containing water, but dry externally. The smoke ascending from a cigar casts moving shadows upon the silken screen. If a small ball be fixed upon the left discharging-rod in place of the point the shadow on the silk is poor, but a second shadow is observed upon the surface of the ball, and this is excessively small, reminding one of the diminished erect virtual optical image in a small polished ball. This one experiment succeeds best if the ball be made the positive con-

ductor. For the other experiments it makes little difference whether the electrification of the point be positive or negative, except that when the point is positively electrified the illuminated surface is a little larger than when negatively electrified. A larger disk of light can also be obtained by working the machine at a greater velocity, but at the same time the shadows are rather smaller.

Prof. Holtz has also obtained the inverse phenomenon of *luminous-figures* by two different means. If two pointed needles are fixed horizontally side by side upon the discharging rod opposite to the disk, there appears a vertical streak of light across the glimmering field. If the needles be replaced by a horizontal strip of metal with its edge directed toward the disk, a vertical bright streak is also produced. A short metallic tube affixed to the discharging rod produces on the disk a dark central spot surrounded by a nebulous bright ring. The second kind of *luminous-figures* is produced in the manner shown in Fig. 2, where a circular disk of metal or cardboard having a central aperture of recognisable form is interposed between the point and the screen. The result is a luminous image of the aperture which, though well-defined at the middle, is marred at the outer regions, the shadowed portions appearing to encroach more upon the illuminated parts as we pass to the peripheral region. The following experiment is curious :—If a square aperture be chosen, the luminous figure projected on to the silken surface shows well-defined corners; but if a small round disk of card be interposed between the discharging point and the square aperture the luminous square on the silken screen at once exhibits rounded corners.

Another interesting point connected with the shadow-figures is that they can be fixed in a temporary manner, like Lichtenberg's figures, by sifting upon the silken surface lycopodium-powder or other fine dust. This collects chiefly upon the contours of the figures, though under certain conditions the luminous and shadowed parts exhibit a contrasted density in the deposit of dust upon them. These dust-figures have an obvious relation with those obtained by Wiedemann from the discharge of Leyden jars through a pointed conductor against the surface of various bodies. It would be interesting to ascertain whether by this process also shadow-figures can be produced.

In explanation of these appearances Prof. Holtz propounds the view that they are due to a rectilinear discharge of electrified particles from the point of the discharging-rod, the discharge taking the general form of a cone, but in which the paths of the outermost particles diverge more widely as they approach the silken disk. The function of the silk he believes to be to retard the discharge, and thereby to increase the electric density on the point. The conducting bodies which are interposed in order to produce shadows act therefore by deflecting the flying particles from their path, either by absorbing or reflecting them. In many cases this action would appear to be a repulsion, since the shadows are always larger than the objects, and suffer more distortion by enlargement nearer the borders of the disk. To explain the production of the double shadows, the rather doubtful hypothesis is advanced that there is a rectilinear discharge of particles in both directions at once.

Quite independently of these observations, the same kind of phenomena have been investigated in America by Messrs. Fine and Magie of the Green School of Science, Princetown, N.J. These experimenters were aware of the existence of shadows on the positive discharging knob, but believed that they were the first to discover the existence of a negative shadow. They found however that non-conductors cast the best shadows, and added the interesting observation that the lines of electrical action were deflected by the presence of a conducting body at the side of the field, and the form of the shadow correspondingly altered. Negative shadows were also observed, they remark, some years ago by Prof. C. A. Young.

These shadow-figures become doubly interesting when compared with the "molecular-shadows" obtained by Crookes from electric discharges in high vacua. Further experiments are probably needed before their precise nature is fully known. S. P. T.

BEN NEVIS OBSERVATORY.

A PROPOSAL was made a year or two ago to erect an observatory on the top of Ben Nevis for meteorological observations, but nothing was done owing to the want of the necessary funds. A committee has been formed, however, within the last few months for the purpose of raising a testimonial to Mr. David Hutchison, who did so much in opening up the West Highlands to tourists with his steamboats, and we observe that it is proposed that the testimonial take the shape of an observatory on the top of Ben Nevis. The committee is a large and influential one, and the proposed scheme has every appearance of being successfully carried out.

In the meantime the Scottish Meteorological Society has commenced daily observations on Ben Nevis, which will be continued during the summer months—the Society having accepted a handsome offer by Mr. C. L. Wragge, who has had experience of such work, to climb to the top of Ben Nevis every morning in time to make observations there at 9 a.m. A complete set of the best instruments has been procured. The barometer (a *Fortin*), is an excellent instrument, and is constructed to read as low as 23·000 inches, in the procuring of which Mr. Scott of the Meteorological Office kindly gave his assistance. On Tuesday, May 31, Mr. Wragge, with Mr. Livingstone, of the Public Schools, and nine workmen ascended the mountain, and the instruments were fixed and secured in proper positions, and all, including the barometer, were found to be in good working order. The regular observations began on the following day, June 1, Mr. Wragge being at his post on the top of the Ben, 4406 feet above the sea, at 9 a.m. He remains an hour at the top, and makes three observations, viz. at 9, 9.30, and 10 a.m. Even during the stormy weather of Saturday last, the observations were made and the observer back to Fort William at 1.30 p.m., on which occasion the temperature at the top was as low as 28°·0.

Simultaneously with the Ben Nevis observations, a complete series of observations are also made near sea-level by Mrs. Wragge. These observations, together with the observations made at the neighbouring stations of Roy Bridge, Corran, Landale, Airds, Lismore, and Dalnaspidal (1450 feet above the sea), will give the data required in dealing with some of the more important problems in meteorology.

NOTES

AMONGST the few existing institutions for the higher education of women, perhaps none has done better work during the last thirty years in a quiet, unobtrusive fashion than Bedford College, York Place. The recent action of London University in opening its degrees to women has given a fresh impetus to women's education; and Bedford College has set itself the task of providing the training for which London University offers only the test—a task in which it has already achieved such success as to give a sure promise of a brilliant future. The funds, however, at its disposal, derived mainly from the bequest of the late Mrs. Reid, prove inadequate to the strain thus put on its resources, and an appeal for support is now being circulated which deserves the attention of the friends of education. In that appeal details of the work and aim of the College will be found. Space will only allow us to add that subscriptions will

be received by the hon. secretary, Bedford College, 8 and 9, York Place, W.

AMONG the houses of historical interest on which the Council of the Society of Arts have just erected memorial tablets, is No. 35, St. Martin's Street, Leicester Square, in which Sir Isaac Newton lived for some time.

M. LITTRÉ, the eminent philologist and philosophical writer, died on the 1st inst., at the age of eighty years. His celebrated French dictionary is probably the best dictionary ever published in any language; not only is its method thoroughly scientific, but it contains nearly every important scientific term in use in French scientific literature.

LAST night a complimentary dinner was given at Freemasons' Tavern to Dr. Danford Thomas, the new Coroner for Central Middlesex. Over a hundred representatives of the various professions were present. Dr. B. W. Richardson was in the chair.

THE *conversazioni* of the Society of Arts and the Civil Engineers, on Thursday and Friday last, were as usual successful; over 2000 people were present at each.

THE anniversary meeting of the Vienna Academy was held on May 30. R. Maly, Professor of Chemistry at Gratz, and F. Lippich, Professor of Physics at Prague, were elected correspondents.

THE Dundee Naturalists' Society have three dredging expeditions in their programme of excursions this summer—one on June 11 to St. Andrew's Bay, a second on July 20 to the Bell Rock, and a third on August 31 to Lunan Bay.

MR. EDISON has written to M. Georges Berger, asking for 120 horse-power to work the large generator he is sending to Paris for the forthcoming exhibition.

EXPERIMENTS are being made with a view to running trains through the St. Gothard Tunnel by electricity, with motive power obtained from the Reuss and the Tessin. The boring of the Arlberg tunnel proceeded last month at the rate of six and a half metres per day. The making of the lines of access will hortly be undertaken.

AT an examination held by the Sanitary Institute of Great Britain on June 2 and 3, six candidates presented themselves, and the Institute's certificate of competency as Local Surveyor was awarded to Samuel S. Grimley and to Arthur Whitcombe, and the Institute's certificate of competency as Inspector of Nuisances was awarded to John Latein Cowderoy, to Joseph Rains, and to William Wilkinson.

WE have received a copy of a paper by J. H. Collins, F.G.S., published in the *Journal* of the Royal Institution of Cornwall, No. xxiii., which contains analyses of the new minerals Henwoodite, Enysite, Duporthite, Penwithite, as well as of other minerals and rocks. Good analyses of minerals are always useful for reference; and Mr. Collins is rendering a service to science in publishing the results of his work. His paper would have been more valuable had he mentioned the methods employed for separation and determination of the mineral constituents, as, for instance, in the analyses of minerals containing alumina, iron, and phosphoric acid. It would likewise save trouble if the percentage composition of his assumed formulæ for minerals were placed in parallel columns with the quantities obtained. That they agree "fairly well" is a little vague.

THE earthquake shocks on Mount Vesuvius were followed on the 1st inst. by a strong eruption. Broad and active streams of lava ran quickly down the north-east side of the mountain.

A SHOCK of earthquake occurred at Serajewo (Bosnia) on June 2, at 4h. 40m. a.m., duration 2 sec.

ON the 1st inst. the Duke of Edinburgh placed the top stone on the new Eddystone Lighthouse. The stonework of the structure has now been completed after a labour of three years. The lantern has yet to be placed on the top of the structure, and the illuminating apparatus has to be fixed, and all the internal fittings are to be applied, but this is work that can be carried on at any time of the tide, so that the whole of the work will, it is expected, be completed in another year, twelve months within the period stipulated in the contract.

IN a report on the health of Swatow, just published by order of the Inspector-General of Chinese Customs, Dr. E. J. Scott refers to a plague of caterpillars which visited the neighbourhood last summer, literally covering the fir trees, on which they lived exclusively, and leaving them perfectly denuded of leaves. The hill sides in many places looked as if a fire had passed over the trees and scorched them. The Chinese were very much afraid to handle these caterpillars, as they declared that they were exceedingly poisonous, and Dr. Scott says they are to some extent right, as he knew of two foreigners who were injured by them. When crushed, they exuded a glutinous fluid of a light-green colour, very irritating to the skin, and producing rash, which caused much inconvenience for ten days or a fortnight.

DR. HAHN has recently published a work, in which he gives photographic reproductions of more than one hundred thin sections of meteorites on thirty-two plates. In that class of meteoric stones which bear the name of chondrites, on account of the curious round nuclei they contain, Dr. Hahn believes he can demonstrate the existence of a whole series of organic forms belonging to the animal world. A number of the sections shows a structure closely resembling corals. Dr. Weinland publishes an article on this subject in No. 16 of the *Ausland*, Dr. Hahn having placed the thin sections at his disposal; and he states that he gained the conviction that he was really beholding remains of animals belonging to the family of Favosites, well known among Silurian, Devonian, and Coal fossils. For further information we must refer our readers to the article mentioned.

AN epidemic among the crayfish of all the rivers and rivulets of the Stettin district has led to the complete destruction of that crustacean in those waters.

IN the north of France great devastation is caused by large field-mice (*Arvicola arvalis*) among the crops. The plague is particularly severe in the departments of Seine-et-Oise, Eure-et-Loire, Loiret, Seine-et-Marne, Yonne, Aube, Marne, and Haute Marne.

"LA BELLE JARDINIÈRE," one of the largest clothing establishments in Paris, is employing with success magneto-electric machines for the transmission of power, from the basement to the top of the building. The two machines have been built by Siemens Brothers.

AN opera performed on the stage of the Paris Grand Opera House was heard satisfactorily at the Rue Riche Opera House by a number of French officials a few days ago. The feat was performed with the new Ader telephone, of which the peculiarities have not been made public. The performance will be repeated at the International Exhibition.

M. MEREJKOFFSKY's report on his anthropological journey in the Crimea (*Izvestia*, 1881, fasc. 2) contains interesting measurements of skulls of the Crimean Tartars—the pure Steppe Tartars who do not present a mixture with Greeks, as the south-coast

Tartars do, nor with the Nogaï, who are now, however, not numerous. After having measured the skulls of about 200 persons, he finds that the cephalic index is: 0·908 for children from 4 to 7 years old, 0·882 from 8 to 9 years, 0·876 from 10 to 12 years, 0·871 from 13 to 14 years, 0·852 from 15 to 19 years, and 0·845 from 20 to 23, being the average from 82 measurements. When discussing the figures received for 27 very pure representatives of Tartars, he shows that the maximum figures were, in four cases, from 0·886 to 0·903, and the minimum in two cases, 0·789 and 0·800; for the 21 others the index varies comparatively little, namely, from 0·822 to 0·876. M. Merejkoffsky has observed among the Tartar women the use of tattooing in small spots between the eyebrows and on the forehead. As to the staining the nails red, which is spread everywhere among the women, and sometimes also among men, M. Merejkoffsky, after having discussed the same custom among other peoples, arrives at the conclusion that it is a survival from the time when the whole skin was stained with red, originally with the blood of enemies, to inspire dread.

THE geysers of Whakarewarewa, New Zealand, are stated to have lately been in a state of agitation, throwing hot water to a great height. The natives anticipated still further eruptions. The geysers have been dormant for six months.

THE Annual Report for 1879-80 contained in the *Proceedings* of the Norwich Geological Society complains of the little interest taken in the work of the Society by the members; the bulk of the work seems to be done by the members of the Geological Survey stationed in the neighbourhood. The presidential address, by Mr. J. H. Blake, "On the Age and Relation of the so-called 'Forest-bed of the Norfolk and Suffolk Coast,'" is of considerable interest. It has been separately reprinted. Among the other papers is one on "The Subdivisions of the Chalk," by Mr. A. J. Jukes-Browne.

THE Twenty-Third Report of the East Kent Natural History Society contains some of the more important papers read during the year. We regret to see that the interest of some of the members in the welfare and work of the Society is not so great as it might be, and that, as in not a few similar societies, the bulk of the work falls on the shoulders of a few of the more energetic members.

WE are glad to find a decided improvement in No. 1, vol. x. of the *Canadian Naturalist*. The papers are mostly geological, a large proportion are original, or at least of purely Canadian origin, and all of scientific value. Principal Dawson contributes some important Palæontological Notes, and there is a long paper by Mr. R. Chalmers on the Glacial Phenomena of the Bay Chaleur Region, with a map. Dr. G. M. Dawson writes of the Geology of the Peace River Region. Appended are Meteorological Notes for 1880, and a curious statement as to the Niagara Falls having been dry for a day, March 31, 1848.

Naturæ Novitates, the fortnightly list of novelties in scientific literature, started some time ago by Friedländer of Berlin, continues we are glad to see, to flourish. It is calculated to be of real service to workers in science.

MR. JOSCELINE BAGOT and Mr. Drummond, of the Grenadier Guards, accompanied by Mr. T. Wright, the winner of the International Balloon Contest, went up in a balloon from the Crystal Palace on the 1st inst. at 1 p.m. When the ropes were loosed they ascended to the height of 5000 feet, and travelled slowly in a south-westerly direction for the distance of about eight miles. The balloon then suddenly sank, but ballast being thrown out, it rose again to 8000 feet, and traversed in the direction of Epsom. The aëronauts then descended in a field about a quarter of a mile from the Grand Stand, which they reached in time to witness the race for the Derby.

SIR R. TEMPLE'S lecture on the lake region of Sikkim is given in the current issue of the Geographical Society's *Proceedings*, illustrated by a capital map and some very good engravings from the author's sketches on the spot. The other papers are a translation from the Russian by Mr. Delmar Morgan of Dr. Regel's account of his expedition from Kuldja to Turfan in 1879-80, and Mr. F. C. Selous' notes on recent explorations in Mashuna-land, the latter of which adds something to our knowledge of the hydrography of the Zambesi basin, and is accompanied by a map in the text showing the routes of Mr. Selous and others. The geographical notes relate chiefly to the work of various expeditions on the Congo and other parts of West Africa. There are also notes of some interest on the true name of the Chukches and on Richmond Gulf, Hudson's Bay. Mr. James Stevenson contributes a memorandum of the longitude of Lake Nyassa, which is followed by a full abstract of the proceedings of the Paris and Berlin Geographical Societies.

THE paper by General Pitt-Rivers announced last week will be read at the Anthropological Institute on the 14th, not 7th inst.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus* ♂) from India, presented by Mr. W. Nugent; a Vulpine Phalanger (*Phalangista vulpina* ♂) from Australia, presented by Master H. Berridge; ten Green Lizards (*Lacerta viridis*), European, presented by Mr. H. N. Moseley, F.Z.S.; two Ostriches (*Struthio camelus* ♂ ♀) from Africa, two White-backed Piping Crows (*Gymnorhina leuconota*), a Laughing Kingfisher (*Dacelo gigantea*) from South Australia, deposited; a Prince Albert's Curassow (*Crax alberti* ♀) from Columbia, two Golden Agoutis (*Dasyprocta aguti*) from Guiana, two Common Boas (*Boa constrictor*) from South America, on approval; a Japanese Deer (*Cervus sika* ♂), a Cuming's Octodon (*Octodon cumingi*), born in the Gardens; five Impeyan Pheasants (*Lophophorus impeyanus*), four Peacock Pheasants (*Polyplectron chinquis*), a Ruddy Sheldrake (*Tadorna rutila*), bred in the Gardens.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

OXFORD.—In a Convocation holden on June 7 a decree was passed, without opposition, to amend the statute relating to the Degree in Medicine. According to the new decree, those who enter their names for the First Examination for the Degree of Bachelor of Medicine, and who satisfy the Regius Professor of Medicine that they have obtained Honours in the School of Natural Science, or that they have passed the Preliminary Honour Examination in the same School, shall not be required to be examined either in Chemistry or in Mechanics and Physics at the First Examination for the Degree of Bachelor of Medicine.

In the same Convocation the statute to enable non-members of the University to pass an examination in lieu of Responsions was also passed without opposition. The first examination in lieu of Responsions will be held towards the end of the ensuing long vacation.

Mr. George B. Ferguson, M.D., Hertford College, has been nominated Examiner in the Natural Science School in place of Prof. Lankester, and Mr. John Watts, M.A., Balliol College, in place of Dr. Odling.

Prof. Sayce announces a public lecture in the Taylorian Institution, June 8, on the ancient Hebrew inscription recently discovered in Jerusalem.

An examination will be held in Exeter College early in October for the purpose of filling up a Natural Science Scholarship, tenable for four years during residence. The age of the Candidates is not limited, but they will be expected to give evidence of sufficient Classical knowledge to be able to pass Responsions. The examination will be in Biology, Chemistry, and Physics. Candidates will be expected to show proficiency in at least two of these subjects, and the Scholar will be

required to read for Honours in Biology in the Natural Science School. The examination will be to a large extent practical, but special weight will be given to comprehension of general principles. Candidates for the Scholarship may obtain further information by application to the Rector, or to W. L. Morgan, Esq., the Lecturer in Biology at Exeter College.

CAMBRIDGE.—Prof. Humphry has given notice of a class in human osteology, to be held by the demonstrator (Dr. Creighton) during the long vacation, commencing July 4; and a class for practical histology (by Mr. Hill), beginning July 7.

Mr. J. W. Clark is continued in the office of Superintendent of the Museums of Comparative Anatomy and Zoology for two years.

The offer of the Cambridge Philosophical Society to make their library available as the nucleus of a general scientific library in the new museums, to be placed under the care of a librarian appointed by the University, has been formally accepted by the Senate.

Inter-collegiate lectures in higher mathematical subjects are offered for the ensuing long vacation by Mr. Allen at St. Peter's, on electro-magnetism; by Mr. Mollison (Clare), on heat; by Mr. Stearn (King's), on hydrodynamics; by Mr. Niven (Trinity), on elasticity; and by Mr. Lewis (Trinity), on vortex motion and viscosity.

NOTTINGHAM.—The following appointments have been made to the professoriate of Nottingham University College:—The Rev. J. F. Blake, M.A., F.G.S., Professor of Natural Science; Dr. J. A. Fleming, B.A., D.Sc. (London), Professor of Mathematics; Dr. Frank Clowes, D.Sc., F.I.C., F.C.S. (London and Berlin), Professor of Chemistry; the Rev. J. E. Symes (Cambridge), Professor of Literature.

AN important memorial to Lord Spencer, Mr. Mundella, and the Committee of Council on Education is now in course of signature, urging the more systematic teaching of science in elementary schools. The suggestions are made in prospect of the fundamental changes which are contemplated in the Code. The memorialists urge that in Standards I., II., and III. systematic Object Lessons should be given which should lead up to the more scientific teaching to be required in the higher standards. These Object Lessons should have reference to three main divisions of knowledge. They should include, first, Shape and Size, and the properties of bodies depending on them; second, Properties of Matter, including a knowledge of the obvious qualities of material and implements; and third, Plants and Animals, with a knowledge of their uses. At present the elementary stages of teaching have to do too little with things and too much with words, and the memorialists suggest that the existing standards favour this. The memorial has already received the signatures of Prof. Max Müller, Dr. Caldicott, Mr. Eve, Prof. Meiklejohn, Prof. Carey Foster, and leading members of many School Boards.

AT the Education Society on June 6, with Dr. Gladstone in the chair, a discussion was held "On Science Teaching in Intermediate Schools." After the opening remarks of the President, Miss Franks, Mr. Lake, Prof. Guthrie, Prof. G. Carey Foster, Mr. Cooke, and other gentlemen, gave the results of their experience or expressed their opinions. The main conclusions were: that natural knowledge should be taught, not from books, but from things themselves; that the lessons should not consist of information committed to memory, but of knowledge acquired by the child's own observation and experience; that by such object-lessons he should be led to observe the natural facts or processes around him and to exercise his powers of comparison as well as of perception, and thus arrive at such generalisations as are within his capacity; that after the first more general knowledge of the common things around him the child should be led along the broad lines of interest to some more special departments of science. In this later stage the reasoning powers of the child will be more called into action, and the knowledge of the teacher will be presented in a more systematised and abstract form, but still in such a way as shall best develop the intelligence of the scholar.

THE promoters of the Stephenson Centenary at Newcastle-on-Tyne have determined to commemorate the occasion by erecting, if funds can be obtained, a building in that town for the use of the College of Physical Science, to be called the Stephenson College. It is estimated that a sum of 20,000*l.* will be required, of which 1000*l.* has been promised by Sir William Armstrong, and 2000*l.* by other friends. The Newcastle College of Physical Science was established and endowed ten years ago by the combined efforts of the inhabitants of the town and the University of Durham.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, May 25.—R. Etheridge, F.R.S., president, in the chair.—Rev. Tom Bullock Hardern, M.A., LL.M., was elected a Fellow of the Society.—The following communications were read:—On the discovery of some remains of plants at the base of the Denbighshire grits, near Corwen, North Wales, by Henry Hicks, M.D., F.G.S.; with an appendix by R. Etheridge, F.R.S., Pres. Geol. Soc. Traces of these fossils were first observed in 1875 by the author in Pen-y-glog quarry, about two miles east of Corwen. Further research has resulted in the discovery of more satisfactory specimens, which have been examined by Messrs. Carruthers, Etheridge, and E. T. Newton. Among them are spherical bodies resembling the *Pachytheca* of Sir J. D. Hooker, from the bone-bed of the Ludlow series, supposed to be Lycopodiaceous spore-cases; also numerous minute bodies stated by Mr. Carruthers to be united in threes, and to agree with the forms of the microspores of Lycopodiaceæ, both recent and fossil; and some fragments, which may belong to these plants, and others, probably belonging to plants described by Dr. Dawson from the Devonian of Canada under the name of *Psilophyton*. The above testify to the existence of a very rich land-flora at the time. Mixed up with the e however are numerous carbonaceous fragments of a plant described also by Dr. Dawson from the Devonian of Canada, which he referred to the Coniferæ, but which is, according to Mr. Carruthers, an anomalous form of Alga. The former called it *Prototaxites*; the latter renamed it *Nematophycus*. Numerous microscopical sections, showing the beautiful structure of this interesting plant from the specimens found at Pen y-glog, have been examined by Mr. Etheridge and Mr. Newton, and their conclusions agree with those of Mr. Carruthers. The evidence seems to show that at this mid-Silurian period the immediate area where the plants are now discovered must have been under water, and that the mixture of marine and dry-land plants took place in consequence of floods on rapid marine denudation. The author indicated that the land-areas must have been to the south and west, chiefly islands, surrounded by a moderately deep sea, in which Graptolites occurred in abundance. The position of these beds may be stated to be about 2000 feet below the true Wenlock series, and about the horizon of the Upper Llandovery rocks.—Notes on a mammalian jaw from the Purbeck beds at Swanage, Dorset, by Edgar Willett. Communicated by the President.

Physical Society, May 28.—Prof. Fuller, vice-president, in the chair.—Mr. C. Woodward exhibited apparatus for illustrating wave-motions to a class. This consisted of a number of glass panes of equal size mounted on stands so that they could be ranged in a line or in rank and file. Patches of blue paper were attached to them to represent the moving particle of the wave, the positions being determined by a diagrammatic card which fitted each pane. A machine for showing Fresnel's conception of polarised light consisted of two axles fitted with a number of cranks which supported a roof of rafters bearing at their ridges a number of beads to guide the eye in tracing the wave-motion. By turning the axles the cranks shifted the frame of rafters, and the beads displayed the wave-motion, which was vertical, elliptical, or circular according to the adjustment.—Prof. G. Forbes explained the experiments made by him and Dr. Young to determine the velocity of light. The method employed was that of Fizeau, but instead of having one distant reflector and observing the total eclipse of the reflected ray by a tooth of the revolving wheel, two reflectors, one a quarter of a mile behind the other, were used, and two rays, which were observed when of equal brightness. This method was found more accurate than Fizeau's own plan, and gave curves of brightness. The speeds of the toothed wheel were adjusted until the two rays appeared of equal brightness. The general result was that the velocity of the light of an electric lamp is 187,200 miles per second. Cornu found the light of a petroleum lamp to be 186,700 miles per second, and Michaelson that of the sun to be 186,500 miles per second. The higher number of Prof. Forbes is probably due to the bluer light of electricity, for further experiments made with coloured lights and the spectrum seemed to prove that blue light travels probably over 1 per cent. faster than red light. The experiments were made at Wemyss Bay, in Scotland. Mr. Spottiswoode, P.R.S., said he had followed Prof. Forbes with interest, and these results appeared to modify our ideas of the luminiferous ether. Lord Rayleigh inquired why it was that Jupiter's satellites showed no difference in tint in emerging from eclipse if red and blue rays travelled with unequal velocities? Prof. Forbes believed it due to the gradual character of the emergence of the satellites from behind their primary. According to the new theory variable stars should however seem bluish with an increase of their light. Prof. G. C. Foster pointed out that dispersion of the light in the air would rather have had the effect of retarding the blue rays. Mr. Hall of Baltimore, U.S., then exhibited the experiment in which a current of electricity flowing longitudinally along a thin foil of metal is caused to yield a transverse or lateral current by inserting the foil between the poles of a magnet. The lateral current is observed on a sensitive galvanometer, and care is taken in the first place to find points of connection with the foil, which yield no current before the magnet is applied. The results were that if iron is called + the series is iron +, silver −, gold −, platinum −, tin −. Curiously, nickel, though a magnetic metal like iron, is −; but on inquiry by Prof. Chandler Roberts it proved that the nickel employed was perhaps impure. Cobalt ranges between iron and silver, and is +, like iron. Prof. Perry suggested that the displacement and huddling of the lines of flow of the current by the magnet might cause the current; but Mr. Hall said that an experiment had been tried to test that, and went to prove that it was not due to crowding of these lines.—The Secretary read a paper by Prof. J. H. Poynting on the change of bodies from the solid to the liquid states. There are two types of change exemplified by ice-water and by sealing-wax: in the one a surface melting at the same temperature, in the other a softening of mass and heating. The first was thought by Prof. Forbes to be a limiting case of the second type, but the author gives reasons for supposing that it is rather an exchange phenomenon analogous to what takes place when water evaporates, and the melting-point is reached when the number of molecules passing from the ice to the water is equal to the number passing from the water to the ice. The sealing-wax type is analogous to the change of state in a liquid-gas above its critical point, where it changes gradually from a rather liquid to a certainly gaseous state.

Anthropological Institute, May 10.—Major-General A. Pitt-Rivers, F.R.S., president, in the chair.—Mr. Hyde Clarke exhibited a collection of stone implements collected by Mr. Papadopoulo Keramenes of Smyrna.—Lieut.-Col. R. G. Woodthorpe, R.E., read a paper on the wild tribes of the Naga Hills.—Prof. G. Dancer Thane read a paper on some Naga skulls.

May 24.—Major-General A. Pitt-Rivers, F.R.S., president, in the chair.—Mr. E. H. Man read a paper on the arts of the Andamanese and Nicobarese. After exhibiting and describing the new objects from the Andaman and Nicobar Islands, comprised in the second collection recently presented by him to General Pitt-Rivers, the author gave a slight sketch of the aborigines of the former group; he stated that they are divided into at least nine tribes, linguistically distinguished, and in most, if not all, of these there are two distinct sections, viz. inland and coast men. In confirmation of this

statement Mr. Man read a translation he had made of an account obtained in 1876 from a member of the inland branch of the Awko jûwai tribe, inhabiting a portion of the Middle Andaman, regarding their habits and mode of life, the details of which had since been fully corroborated. In many mental characteristics affinity to the Papuans would appear to exist, and the standard in social and marital relations is shown to be far higher than could be expected from a race so entirely outside the pale of civilisation; the previous accounts of their laxity in this respect are now proved to be erroneous. They have no forms of religion or ideas of worship, and though they have faith in a Supreme Being, the Creator, their belief in the Powers of Evil is much more strongly developed. The habitations of the eight tribes of Great Andaman are of three varieties, partaking almost invariably of the nature of a simple lean-to, while those of the remaining tribe, Jârawa-(da), are somewhat similar in form to the huts erected by the Nicobarese. The rights of private property are recognised and respected; there also appears to be a fair division of labour and perfect equality between the sexes in their social intercourse.—Dr. Allen Thomson, F.R.S., read a paper on some bone necklaces from the Andaman Islands. Several of the specimens exhibited by the author were constructed entirely of human bones, while some were composed of bones of various animals, and others were partly made up of pieces of coral.—Mr. J. Park Harrison, M.A., exhibited an incised slate tablet and other objects from Towyn. The figures upon the slate appeared to represent celts, urns, &c.

Photographic Society, May 10.—J. Glaisher, F.R.S., president, in the chair.—Mr. Leon Warnerke read a paper on a new discovery regarding gelatine emulsion. This consisted in the observed fact that when gelatine emulsion has been submitted to the combined action of light and pyrogallic acid, it becomes insoluble in warm water; a gelatine negative is transferred to glass or paper, and from the back, with warm water, all parts not acted upon by light and the developer can be washed away; consequently a solvent of the silver not acted upon, such as hypo-sulphite, becomes unnecessary, and the remaining film or picture is left intact, and from its purity can be reacted upon in many ways hitherto extremely difficult or impossible. This discovery also becomes valuable in its application to the Woodbury printing process, phototype printing, and burnt-in photography on ceramic ware.

Institution of Civil Engineers, May 31.—Mr. Abernethy, F.R.S.E., president, in the chair.—The paper read was on "The Production of Paraffin and Paraffin Oils," by Mr. R. Henry Brunton, M. Inst. C.E.

PARIS

Academy of Sciences, May 30.—M. Wurtz in the chair.—The following papers were read:—Memoir on the temperature of the air at the surface of the ground and down to 36 m. depth, also the temperature of two pieces of ground, the one bare, the other covered with grass, during 1880, and on the penetration of frost into these, by MM. Becquerel. The effects of the severe cold receive special attention. The screening influence of snow is shown. *Inter alia*, the propagation of frost is slower in grassy ground than in bare ground. In the latter the rate increases very slightly with the depth, the propagation being very regular. In grassy ground the increase is very notable, and with increasing depth, the rate tends to come near that in bare ground. Each layer of ground is subject to two calorific effects: one due to variations of external temperature; the other to the action of deep layers which tend to give a constant temperature.—On rabies, by M. Pasteur, with MM. Chamberland, Roux, and Thuillier. The seat of the virus is not in the saliva alone; the brain contains it, and the authors have successfully inoculated with brain substance. They have also succeeded in shortening the time of incubation, inoculating directly the brain of a dog with cerebral matter from a mad dog (and having recourse to trepanation).—Nebulæ discovered and observed at Marseilles Observatory, by M. Stephan.—On the theory of motion of celestial bodies, by M. Gyldén.—On a new means of accelerating the service of canal-locks, by M. De Caligny.—On the genera *Williamsonia* Carruth. and *Goniolina* D'Orb (continued), by MM. de Saporta and Merion.—Observation and elements of the comet *a* 1881 (L. Swift), by M. Bigourdan.—On Fuchsian functions, by M. Poincaré.—Algebraic relations between the superior sines of a given order, by M. Rouyaux.—On the sines of superior orders, by M. West.—On the discontinuous phosphorescent spectra observed in almost perfect vacuum, by Mr. Crookes. M. Edm. Becquerel recalled his own spectroscopic studies of the light of phosphorescent substances and his excitation of such substances by submitting them to the discharge in vacuum tubes (in which case the rise of temperature and the electric light itself complicated the effects).—New interrupter for induction-coils, by M. Deprez. A claim of priority (to M. Ducretet) on the conical mirror; reply to a communication of M. Pifre, by M. Mouchot.—Discussion of the theory of three fundamental colour sensations; distinctive character of these colours, by M. Rosenstiehl. Certain properties attributed to primary colours do not belong to them exclusively, *e.g.* their producing all perceptible colours when mixed two and two, and the sensation of white arising from the three fundamental sensations being excited equally. The fundamental property of the primary triad is stated to be that colours situated on either side of a primary colour (in the graphic triangle) and equidistant to sight have their complementaries so near together that it becomes difficult to distinguish those which are consecutive.—On the oil of wild thyme, by M. Febve.—On geological microzymas; reply to MM. Chamberland and Roux, by M. Béchamp.—On a vanadate of lead and copper of Laurium, by M. Pisani.—On the existence of the Cambrian formation at Saint Léon and Châtelperron (Allier), by M. Julien.—On the coal-formation of Commentry; experiments made with a view to explain its formation, by M. Fayol. He reproduced the conditions and effects on a small scale by means of basins with a constant level of liquid, receiving currents of water with pebbles, sand, clay, coal, plants (previously immersed some time, so as to sink in quiet water), &c.—Movements of the frog consequent on electric excitation, by M. Richet. Frogs (intact) show great resistance to electric stimuli. (Two Thomson elements were used, with a coil.) The response to a single stimulation of the leg or sciatic nerve was generally more than 0·15 seconds after; the delay was oftener half a second, sometimes as much as ten seconds. With repeated excitations the reaction is sometimes extremely slow. In general the response is more rapid the stronger the excitation. Fatigue comes quickly. Excitations of the sensibility stop voluntary movements. The general movements of flight or defence in intact frogs, on electric excitation, seem to be determined by the bulb. Are they (M. Richet asks) reflex or voluntary?—On symmetrical vaso-motor actions, by MM. Teissier and Kaufmann. Under certain conditions the reverse of the law established by Brown-Séquard and Tholozan holds good; a capillary dilatation on the left side, *e.g.* will produce a vascular constriction on the right side, or *vice versâ*.

VIENNA

Imperial Academy of Sciences, June 2.—M. Burg in the chair.—E. Hornstein, contribution to a knowledge of the system of asteroids.—Prof. S. Stricker, on the law of convulsive action.—Dr. Ludwig Langer, on the chemical composition of human fat at different ages.—Prof. E. Zuckerkandl, on the communications of the venæ pulmonales with the bronchial veins and the veins of mediastinum.—Prof. W. Loebisch and Dr. A. Loos, on glycerin-xanthogenates.—Dr. P. Wesselsky and Dr. R. Benedikt, on hydroquinonic and orcinic ethers.—Dr. L. Szajnocha, contribution to a knowledge of Jurassic Brachiopoda of the Carpathian rocks.—Prof. T. Finger, on an analogon to Kather's pendulum and its use for measuring gravitation.—Dr. S. Ehrmann, on the determinations of nerves in the pigment-cells of frogs' skin.

THE STORAGE OF ELECTRIC ENERGY

I AM continuing my experiments on the Faure accumulator with every-day increasing interest. I find M. Reynier's statement, that a Faure accumulator, weighing 75 kilograms (165 lbs.) can store and give out again energy to the extent of an hour's work of one-horse power (2,000,000 foot-pounds) amply confirmed. I have not yet succeeded in making the complete measurements necessary to say exactly what proportion of the energy used in the charging is lost in the process of charging and discharging. If the processes are pushed on too fast there is necessarily a great loss of energy, just as there is in driving a small steam-engine so fast that energy is wasted by "wire-drawing" of the steam through the steam pipes and ports. If the processes are carried on too slowly there is inevitably some loss through local action, the spongy lead becoming oxidised, and the peroxide losing some of its oxygen viciously, that is to say, without doing the proper proportion of electric work in the circuit. I have seen enough however to make me feel very confident that in any mode of working the accumulator not uselessly slow, the loss from local action will be very small. I think it most probable that at rates of working which would be perfectly convenient for the ordinary use of fixed accumulators in connection with electric lighting and electric transmission of power for driving machinery, large and small, the loss of energy in charging the accumulator and taking out the charge again for use will be less than 10 per cent. of the whole that is spent in charging the accumulator: but to realise such dynamical economy as this prime cost in lead must not be stinted. I have quite ascertained that accumulators amounting in weight to three-quarters of a ton will suffice to work for six hours from one charge, doing work during the six hours at the uniform rate of one-horse-power, and with very high economy. I think it probable that the economy will be so high that as much as 90 per cent. of the energy spent in the charge will be given out in the circuit external to the accumulator. When, as in the proposed application to driving tramcars, economy of weight is very important, much less perfect economy of energy must be looked for. Thus, though an eighth of a ton of accumulators would work very economically for six hours at one-sixth of a horse-power, it would work much less economically for one hour at one horse-power; but not so uneconomically as to be practically fatal to the proposed use. It seems indeed very probable that a tramcar arranged to take in, say 7½ cwt. of freshly-charged accumulators, on leaving head-quarters for an hour's run, may be driven more economically by the electric energy operating through a dynamo-electric machine than by horses. The question of economy between accumulators carried in the tramcar, as in M. Faure's proposal, and electricity transmitted by an insulated conductor, as in the electric railway at present being tried at Berlin by the Messrs. Siemens, is one that can only be practically settled by experience. In circumstances in which the insulated conductor can be laid, Messrs. Siemens' plan will undoubtedly be the most economical, as it will save the carriage of the weight of the accumulators. But there are many cases in which the insulated conductor is impracticable, and in which M. Faure's plan may prove useful. Whether it be the electric railway or the lead-driven tramcar, there is one feature of peculiar scientific interest belonging to electro-dynamic propulsion of road carriages. Whatever work is done by gravity on the carriage going down hill will be laid up in store ready to assist afterwards in drawing the carriage up the hill, provided electric accumulators be used, whether at a fixed driving station or in the carriage itself.

WILLIAM THOMSON

University, Glasgow, June 13

THE LIFE OF WHEWELL

The Life, and Selections from the Correspondence, of William Whewell, D.D., late Master of Trinity College, Cambridge. By Mrs. Stair Douglas. (C. Kegan Paul and Co., 1881.)

IT is now about four years since the first instalment of a biography of the late Dr. Whewell was published. These volumes, admirably edited by Mr. Todhunter, give us a brief outline of his history, but consist chiefly of a most valuable analytical account of his writings and a selection from his literary and scientific correspondence. In the preface a more complete memoir of Dr. Whewell's personal and domestic history is announced as in preparation. The present volume, edited by Dr. Whewell's niece, Mrs. Stair Douglas, fulfils the promise then given. The preface explains the long interval—fourteen years—which has elapsed since Dr. Whewell's death. A series of untoward events have continued to retard publication. From various causes much delay occurred before the exact plan of the work was determined and the subjects apportioned. At first it was hoped that what may be called the academic life of Dr. Whewell would be undertaken by Mr. Aldis Wright, the present Bursar of Trinity College. But the pressure of heavy and unavoidable engagements has precluded him from proceeding with the task. Mrs. Douglas then endeavoured to work the materials into the selections from Dr. Whewell's personal correspondence which she had nearly completed, with the assistance of Mr. J. Lemprière Hammond, Fellow of Trinity, and one of Dr. Whewell's executors. Before this was accomplished she was deprived of his invaluable aid by his lamented and untimely death. Thus some portions of the present work are a little incomplete. Still, as these are generally of a rather technical nature, and more interesting to members of the University than to the general reader, their absence probably will not be very widely felt. We may be allowed to express our admiration at the tact and good taste with which Mrs. Douglas has executed her task. She allows Dr. Whewell as far as possible to speak for himself, connecting his letters generally with only such brief biographical paragraphs as are necessary for a connected and intelligible narrative. There is little comment and no attempt at the fulsome praise with which biographies are often disfigured. Her descriptions, though brief, are often graphic, while the letters enable us to see the Master of Trinity as he appeared to the inner circle of intimate friends and loved relations.

Of his vast and varied knowledge it is almost needless

now to speak. Suffice it to say that the letters now published contain additional testimony to the truth of Mr. Todhunter's remark in his preface to the volumes mentioned above: "I do not think adequate justice can be rendered to Dr. Whewell's vast knowledge and power by any person who did not know him intimately, except by the examination of his extensive correspondence; such an examination cannot fail to raise the opinion formed of him by the study of his published works, however high that opinion may be."

The letters, however, in the present volume, as might be expected, bring out their author in a light which is to many new and unexpected. To most persons that broad forehead with its massive brow seemed indicative of intellectual strength almost gigantic; the square shoulders, strong bones and muscles, the swinging gait—with which as he swept along he seemed to shoulder aside weaker men by the very waft of his passing—told of irresistible force of will and energy of purpose; tenderness of heart seemed improbable in one of such Titanic mould; one deemed him a "man of iron," who, had he chosen a field other than literature and science, might also have been one of blood; but, as we shall presently see, underneath that rough exterior there was a warm and affectionate heart concealed.

Of the childhood of William Whewell but few particulars are recorded. A master-carpenter's son at Lancaster, he was on the point of quitting the Blue Coat School in that town to be apprenticed to his father, when—by a mere chance as it seemed—the head-master of the Grammar School entered into conversation with the boy, and was so struck by his abilities that he persuaded the father to let his son come to that school, generously offering to give him both books and instruction. According to Prof. Owen—probably his sole surviving schoolfellow—the lad's indomitable spirit soon manifested itself, as well as his appetite for work. The latter indirectly raised the standard of the school lessons, and the other boys threatened to "wallop" him as the penalty for preparing more than twenty lines of Virgil. Even then however this was more easily said than done, and the "wallopers" got as good as they gave, until public opinion in the school decided that it was unfair for more than two boys to attack him at once—"after the fate of the first pair, a second was not found willing." Once only did Whewell shock the moral feelings of his revered master, and that was when an undergraduate at Trinity. The crime shall be told in the master's own words: "He has gone and got the Chancellor's gold medal for some trumpery poem, 'Boadicea,' or something of that kind, when he ought to have been sticking to his mathematics. I give him up now. Taking after his poor mother, I suppose." (She had occasionally contributed to the "Poet's Corner" of the local newspaper.) Mrs. Owen, to whom this complaint was made, pacified the worthy man by remarking that "young men must have some amusement, and this seemed to be a very innocent one."

Notwithstanding Dr. Whewell's strong frame he appears to have suffered from some constitutional delicacy when a lad. His mother—evidently a woman of ability and culture above her station—died when he was thirteen; his father only survived to see him take a degree. A sister also died young; and of his three brothers two died in infancy and the other at the age of nine. Talent was evidently hereditary in the family, for the little brother, at seven years old, had begun to write English verses, and one of his sisters habitually wrote poems. Of all three of the latter, he says, when referring to his prize poem, in a letter to his father, "I am happy in having sisters who all of them have, I think, a more rational taste for poetry and literature of all kinds than any other girls in the same circumstances."

It is very interesting to note the gradual change in these letters. We see in them not only the unfolding of his great intellectual powers as evidenced by the widening circle of interests, but also the gradual expanding of the moral nature. At first those addressed to his relations and more intimate friends are a little stiff and cold, but as sorrows succeed one another the religious element in Dr. Whewell's character becomes more conspicuous, and the later letters are marked by a depth of tenderness surprising to those who only knew him slightly. He was devotedly attached to his first wife, and almost heart-broken by her loss. In one letter he describes himself as taking no pleasure in success now that she was gone, and tells his niece how, while he sat as Vice-Chancellor in the Senate-house conferring degrees, he felt so lonely and miserable that the tears kept trickling down his face; "so unlikely a thing in a Vice-Chancellor in his chair that probably nobody saw it. I hope so." The writer of this article, who received his degree on that occasion, well remembers some of his friends commenting on the Vice-Chancellor's obvious "sourness" of manner, and wondering whether he was disgusted at the Senior Wrangler being a man of a rival college. We little thought that this was "none other than sorrow of heart." After some time Dr. Whewell married again, his second wife being Lady Affleck, sister of his friend Robert Leslie Ellis. In her companionship he found great happiness, but after about seven years of married life he was again left alone. This time he appeared unable to rally from the bereavement; "the future which intervened between him and the grave dismayed him by its dark desolation." After this he visibly declined; the torpor of age began to steal over his faculties, and many thought that the years of waiting would not be very many; but they were briefer than any expected. While still comparatively vigorous, a fall from his horse caused fatal injury to the brain, and after lingering for a few days, happily without much suffering, he died on March 6, 1866.

"While life was ebbing fast away on that last morning, blinds and curtains were drawn wide apart in compliance with his wish that he might see the sun shine on the Great Court of Trinity, and he smiled as he was reminded that he used to say the sky never looked so blue as when seen fringed with its turrets and battlements. Almost to the last he was conscious, and the last words intelligibly uttered, when the striking of the clock roused him as day dawned, were, 'The Eternal God is my refuge, and underneath are the everlasting arms.'"

The extraordinary comprehensiveness and versatility of Dr. Whewell's mind is fully depicted in the letters published in Mr. Todhunter's volume, but it is brought out no less, perhaps even more, graphically by some of the brief allusions in his familiar correspondence. This, for example, is one taken from a letter to his sister: "Besides my usual employments [as College Tutor and

Professor of Mineralogy] I have to go to London two days every fortnight as President of the Geological Society, and am printing a book which I have not yet written ["The History of the Inductive Sciences"], so that I am obliged often to run as fast as I can to avoid the printers riding over me, so close are they at my heels. I am, in addition to this, preaching a course of sermons before the University; but this last employment, though it takes time and thought, rather sobers and harmonises my other occupations than adds anything to my distraction." He seemed to be able to turn his hand to anything, and, like a dexterous conjuror, play with half-a-dozen balls at once. Pendulum experiments, theories of the tides, mathematical problems, crystallographic formulæ metaphysics, and various subjects in moral philosophy, classics, modern languages, architecture, geology, with plenty of work in general literature, all make up what we may call in the best sense "farrago libelli." These letters also bring out very clearly another characteristic of Dr. Whewell's mind. He was essentially cautious in regard to change—an advocate of reformation rather than of renovation; in science a systematiser rather than a discoverer; like a navigator who explored to the full the uninvestigated coasts of the Old World, rather than one who steered out into the open ocean in the hope of discovering a New World. This was no doubt partly due to his mathematical training and academic habits of life—but it is very rare, perhaps impossible, to find a memory of extraordinary tenacity and a life essentially studious, combined with originality in one of its highest forms. That requires a good deal of mental fresh air, and is apt to droop a little if too much confined to the atmosphere of a library. This is especially evident in Dr. Whewell's remarks upon the "Vestiges of Creation" and in his essay on the "Plurality of Worlds." The same tone of mind is very conspicuous in his attitude towards the question of University Reform. He was a vigorous opponent of the abuses of private tuition, a zealous advocate of progress in every department of learning, deeply anxious for the improvement of the Classical and Mathematical Tripos examinations, and to him more than to any other single man the recognition of the Natural and Moral Sciences as branches of academic study is due. But he was antagonistic—almost bitterly so—to the appointment of the Royal Commission of 1856 and of its successor, and was hostile in many respects to the changes—now almost universally acknowledged to have been on the whole very beneficial—which were introduced by the statutes of 1859-61. His great hope and desire was that the University should be allowed to reform itself, and be spared any interference from without. That he should have entertained this hope after so many years of academic labour is perhaps the strongest proof of his sanguine temperament.

We must now part from this interesting volume. Perhaps—like the portrait prefixed to it—it slightly fails in depicting the characteristic ruggedness of the man, but it does much to show him as he was to those near and dear to him as well as to the world—a man of immense intellectual power, of intense energy and industry, of high purpose and simple piety, a hard hitter in conflict and a lover of the shout of battle, but too magnanimous to bear ill-will, whether in defeat or victory. Besides this he was a munificent benefactor to his College and his University: one to whom both must long be grateful, and of whom both may well be proud, as having filled a great position in the world of science and literature, and especially as being "the man" (in the opinion of a most competent judge) "to whom, more than to any other single man, the revival of philosophy in Cambridge is due." T. G. BONNEY

OUR BOOK SHELF

Inorganic Chemistry. Adapted for Students in the Elementary Classes of the Science and Art Department. By Dr. W. B. Kemshead, F.R.A.S., F.G.S. Enlarged edition, revised and extended. (London and Glasgow: William Collins, Sons, and Co., Limited.)

THIS work is a typical one. While containing much that is useful and fairly satisfactory, especially from an examination point of view, the whole tendency of the book, considered as an elementary treatise on a branch of natural science, must be strongly condemned.

The leading facts concerning the better-known non-metallic elements and compounds are succinctly stated; the principal reactions of formation and decomposition of these bodies—especially those reactions which unfortunately *must* be "got up" for examination purposes—are arranged in the form of equations; and the simpler arithmetical applications of such equations are illustrated by fully worked-out examples. But chemistry is more than this: facts must be connected together by principles; the connection between fact and theory, and between theory and fact, must be revealed; these two must not be regarded as synonymous, but as mutually dependent; and the reasoning by aid of which theoretical conclusions are reached must be clearly indicated. Chemistry is neither a system of dogmatic assertions nor an accumulation of shibboleths, by the skilful use of which an examiner may make havoc among the Ephraimites crowding to the Jordan of Examination, but a living science.

The principle which is most largely used (or rather misused) in Dr. Kemshead's book is that of Valency; but valency in the hands of this author is deprived of its value as a scientific theory, and becomes an accumulation of fanciful speculations. The basis of the present work is evidently Dr. Frankland's "Lecture Notes"; hence probably the success of the book in preparing examinees for South Kensington (the present is a second and enlarged edition); and is not such success after all of more importance than training chemists or disciplining the mental powers of youth?

The theory of valency is based on the wider molecular theory of matter, which was preceded by the atomic theory of Dalton, itself a development from that system of chemical notation which rested on the combining weights of the elementary bodies. Now it is clear, from many passages, that the author of this book has failed to distinguish combining weights from atomic weights, and atomic from molecular weights: thus on p. 13 we read "these proportions by weight [*i.e.* from the context, these proportions in which "substances unite together chemically"] when reduced to their lowest relative value, and expressed with reference to that of hydrogen, which is usually taken as unity, are called the atomic weights, or combining numbers of the elements." Again, on p. 26, "the *combining weight* of hydrogen being 1, that of oxygen becomes 16; of nitrogen, 14; of carbon, 12," &c. But combining weights are *not* synonymous with atomic weights, and the *combining weight* of oxygen happens to be 8, of carbon 3, and of nitrogen 4·66. The formula weights of compounds are constantly referred to as "atomic and molecular weights." We have such formulæ as $(NH_4O)_2$, CuO_2, &c., stated to be molecular formulæ

molecule is nowhere defined (in a note on p. 57 a casual statement is made as to the meaning of the term); "Avogadro's law," which lies at the basis of the whole modern edifice of chemistry, is conspicuous by its absence; certain statements as to gaseous combination and to "volume weights" are made, it is true (p. 35), but these are incomplete and misleading.

When a theory of valency is raised on so slender and shifting a molecular foundation as is here laid, no wonder that the edifice should be a strange one; the definition of "atomicity" on pp. 54-55 is incomplete, and cannot be upheld by facts; the statement on p. 58, "it is then a law to which there are no real exceptions, that though the equivalence of an element may vary, it does so always by the addition or subtraction of an even number," is simply untrue. As an "important conclusion" from certain "facts" (? fancies) "on equivalence," it is stated that (p. 59) "a formula which possesses an uneven number of bonds or units of chemical affinity cannot possibly represent a molecule"; without minutely criticising the expression "bond or unit of chemical affinity," suffice it to say that such a formula as, according to Dr. Kemshead, cannot possibly represent a molecule, unfortunately does represent a molecule. The existence of the molecule NO is a case in point: *à propos* of this compound, there is a charming example of the author's method of treating chemical science as a collection of opinions of various authorities to be found in a footnote on p. 169.

Notes on the Crania of New England Indians. By Lucien Carr. From the Anniversary Memoirs of the Boston Society of Natural History, 1880.

THIS is one of the numerous contributions now being made towards our knowledge of the fast-disappearing race of North American Indians. The author, Mr. Lucien Carr, holds the office of Assistant Curator to the valuable Museum of American Archæology and Ethnology at Cambridge, Mass., an institution owing its foundation to the liberality of Mr. Peabody, so well known in England by his benefactions to the London poor, and its scientific excellence to the zeal and organising power of its first curator, the late Dr. Jeffries Wyman, and of his successors.

The object of the present memoir is to collect together such information as is still to be obtained regarding the cranial characters of the native Indians of the New England States, the celebrated "five nations" of the early historians of America, who in consequence of their geographical position were among the first of the race to succumb to the inroads of European immigration. Measurements are given of 67 crania, of which 38 are assigned to males and 29 to females. The averages of these measurements give the following results:—A medium cranial capacity, *i.e.* 1436 cubic centimetres for the males and 1319 for the females. A latitudinal index of ·759, showing mesaticephalism verging upon dolichocephalism. The altitudinal index exactly the same. The principal facial indices show orthognathism, with a strong tendency to mesognathism, a mesorhine nose (index 50), and slightly megaseme orbits (index 88 in the males, and 91 in the females). Although these are the average characters of the whole collection, very few, if any, of the individual crania are to be found presenting them. There is indeed no such uniformity among these skulls as may be seen in certain races, such as Eskimos, Bushmen, Fijians, Andamanese, or even Australians. Perhaps it could scarcely be expected in inhabitants of a large continent, presenting great diversities of climatic and other conditions, and with no natural barriers to free migration and intercourse. The examination of these skulls therefore confirms what has been often remarked before, that although in a broad sense the American Indians present a certain community of type, there is great diversity in detail among them, the result probably of a long series of repetitions of the process of breaking up into distinct groups or tribes and reuniting in various combinations.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Conservation of Electricity

IN a recent communication to NATURE (vol. xxiv. p. 78) Prof. Silvanus P. Thompson very kindly mentions my latest memoir on "The Conservation of Electricity," and, as I am glad to find, confirms my views on this subject by stating that he has independently arrived at the same conclusions with myself.

As regards however the question of priority moved by Prof. Thompson, I think I ought to add that an earlier paper of mine, published five years ago, must have escaped Prof. Thompson's attention. This was printed as an abstract in the *Comptes rendus* of the Paris Academy of Sciences for June 19, 1876, under the title, "Extension du principe de Carnot à la théorie des phénomènes électriques. Équations différentielles générales de l'équilibre et du mouvement d'un système électrique réversible quelconque." I there enunciated the law of the Conservation of Electricity in the same terms as now, and also gave the same analytical method for applying it. I beg leave to quote as a proof the following explicit passage from this extract:—"L'équation $\int dm = 0$ a une autre signification plus simple; elle signifie que de l'électricité peut se déplacer, mais ne peut jamais varier en quantité. Ce principe de la conservation de la quantité d'électricité à été admis par les physiciens dans tous les cas connus jusqu'ici, influence, frottement, etc. . . . . Pour que $\int dm = 0$ pour tout cycle fermé, il faut que dm soit une différentielle parfaite." This method I had already applied in 1875 to the phenomena presented by mercury electrodes (*vide Annales de Chim. Phys.* 1875). In fact my latest memoir is merely a renewed attempt to draw, by means of new applications, the attention of physicists to a fact which I cannot help considering as important for the future, viz. that the principle of the Conservation of Electricity is, *as far as analytical applications are concerned*, the exact analogue to Carnot's Principle for Heat.

Paris, Faculté des Sciences, June 5 G. LIPPMANN

Apparent Decomposition of Sunlight by Intermittent Reflecting Surfaces

IT occurred to me that light might be decomposed by interrupting, with a reflecting surface, a ray of light in such a manner that the interruptions may be proportional to the wave-length period of any particular ray forming a part of a composite ray. The experiment is effected in the following way:—

A wheel having bright spokes (the large wheel of a bicycle answers well) is caused to revolve between an observer and the sun, so that a ray of light is reflected to the observer by a bright spoke; then, when 120 spokes pass before the observer per second, violet light shines out vividly; when 65 pass, red appears, and different rates of revolution give different colours. There seems to be a marked relationship existing between the number of spokes which pass by and the wave-length of the two colours mentioned, that of the violet being $\frac{1}{60000}$ inch, and that of the red $\frac{1}{32000}$ inch.

I am now investigating this apparent relationship between spoke-interruption and wave-length for the other colours of the spectrum of white light, and I hope to be able to make known the results shortly. FREDERICK J. SMITH

Taunton, June 4

Symbolical Logic

I AM sorry that Mr. MacColl should have thought that there was any intention on my part to suggest a doubt as to his having

written his papers without having read Boole's "Laws of Thought." I knew that he was very anxious that the fact should be known, and I called attention to it. I could not state it as a fact known to me. His own assurance was the only ground I had, or could have, to go upon, and in assigning this it never occurred to me to doubt his statement, or to think that I was suggesting doubts to others.

As regards my half humorous suggestion that an attitude of slight social repression was desirable towards novelties of mere notation—not towards new conceptions or methods—I feel sure that almost every one who has not a private scheme of his own to protect will agree with me. Few things can be more perplexing to students of any subject than to find one author after another making use of a new notation to express old results (I mean no special reference to Mr. MacColl here, who does not seem to me one of the worst offenders in this way). At the time of writing my "Symbolic Logic" I had between twenty and thirty such schemes before me. Some of these, of course, express really distinct conceptions, or effect improvements in procedure, but most of them do not; we find half-a-dozen different signs standing for the same meaning, and half-a-dozen different meanings assigned to the same sign. I cannot but think that much of this confusion would be avoided if the various authors would take the trouble to inquire what had been already written upon their subject. The only "repres ion" I should like to see introduced consists in the remonstrances of reviewers and students generally against the mere substitution of a new symbol for one which was already in use for expressing precisely the same process or conception. So far from wishing to discourage any attempts to improve on the results of Boole and others, I rejoice to see them, and think that Mr. MacColl himself has done some good work in this way. It would have been better still if he had not disfigured it by a notation which I think makes him regard his results as more original than they really are.

I need not seriously discuss those parts of Mr. MacColl's letter which give his opinion as to the impression which will be produced in other persons by a perusal of my book, and his "impression" that he has "somewhere seen Mr. Venn quoted as holding an opinion very much at variance with" a statement which he misquotes.[1] (By the way, I heartily agree with his "protest against that spirit of criticism which would offer two or three chipped bricks as a fair specimen of a house," &c., and think the chipping of the bricks a happy turn.) The rest of his letter contains criticisms upon my conclusions on a variety of rather intricate speculative questions. Having stated my own views as fully and accurately as I conveniently could only a few weeks ago, in a systematic work, I really must decline to be drawn into repeating them again, in a condensed form, in the columns of a scientific journal, even if the editor would consent to accept them.

Cambridge, June 12

Telephones in New Zealand, &c.

OBSERVING your paragraph on this subject in NATURE, vol. xxiv. p. 88, it occurs to me that the following may be of interest:—When in Wellington and Dunedin, N.Z., at the end of December last, my opinion was asked by the Government Telegraphic officials there upon a pair of ordinary "Edison-Bell Telephones" (not Edison *bell telephones*, as they are too frequently called) which they had just received from the United States for purposes of experiment. A careful trial under various conditions showed me that they were very good average instruments of ordinary delicacy, such as I had seen hundreds of previously in England and the States.

With these instruments, however, Dr. Lemon, the Superintendent of the Postal and Telegraph Service, was able to converse clearly between Wellington and Napier, over an ordinary land line 232 miles in length, while battery currents were passing over the wires on the same posts.

In New Zealand, Telegraphic communication is, and Telephonic communication will be, entirely in the hands of the Government. In Melbourne the telephone-exchange is worked by a private company, but the erection and maintenance of wires is carried out by the Victorian Government at the annual rate of 5/. per subscriber. In Sydney, I regret to say, nothing was being done in this matter. In Honolulu I found (last January) telephonic communication all over the town, but no telegraphs at all. The King of the Sandwich Islands however, Alii Kalakaua, who is shortly expected in England, told me that he greatly needed submarine cables between the various islands. On my return to England I had the pleasure of sending to Sydney materials for a private telephonic line on sugar plantations in the Fiji Islands, and my friend Mr. Frederick Cobb, manager of the Falkland Islands Company, tells me that the line he took out there at my suggestion is a great success.

At Wellington, where the central N.Z. telegraph office is, I was very much struck by the extreme ease with which duplex circuits were worked. Dr. Lemon informed me that it was scarcely necessary to alter the resistances once a week. He showed me a simple little carbon rheostat of his own invention which appeared to answer admirably; it consisted essentially of two pieces of carbon, the closeness of whose contact was regulated by a screw.

On my way home I paid a hurried visit to the central office of the Western Union Telegraph Company in New York (just at the critical time of the absorption by it of the other two companies and the consequent creation of a monopoly), and was greatly surprised to see the extent to which the 16,000 cells in the battery-room were being replaced by Siemens's dynamo-machines. I was told that one of them would "drive" about fifty wires, and was shown a number of plaster-of-paris cylinders, about five inches long and one inch diameter, which were put into circuit to diminish, when necessary, the intensity of the current. It may be remembered that as a rule American lines are less perfectly insulated than ours, and hence require stronger currents.

Implements at Acton

MR. PERCEVAL'S letter in NATURE, vol. xxiv. p. 101, is an interesting one, but the occurrence of Neolithic implements at and near Acton has been known (if not published) for many years past. In the Pitt-Rivers' collection may be seen Neolithic scrapers and flakes from the Acton district. I have found Neolithic stones in the neighbourhood of Acton and Willesden for many years past; and only a few weeks ago I picked up a beautiful and perfect knife of black flint made from a large flake, five and a half inches long, and one and three quarter inches wide, in the field on the east of Acton Station of the North London Railway. Many of the Neolithic flints from this position are white. A considerable number of Neolithic implements and flakes have at different times been dredged up from the Thames to the West of London, and some of these have been quite recently exhibited. I do not attach importance to the quartzite pebble, as pebbles of quartzite are extremely common in the glacial deposits at the North of London, and very common in the gravels of the Thames and its northern tributaries. They also occur *in situ* at the north of Willesden.

Will Mr. Perceval kindly furnish the heights at the Hammersmith position, and say whether he is positive that the gravel he has in view was dug on the spot, and whether the implements occur there (as his letter implies) in "remarkable abundance"? I have repeatedly examined the low gravels about Hammersmith, Fulham, and Chelsea, but with no result. For more than three years I have never missed an opportunity of looking over the low gravels belonging to these places, together with the positions at West Brompton and Kensington, where thousands of tons of gravel have been excavated. My result has been one dubious flake, probably washed down from one of the higher terraces. I however have heard of two Palæolithic implements having been found—one at Kensington and the other at West Brompton—but whether from the local gravel or not I am uncertain.

I by no means wish to imply that because I have been unable to find implements in the lower gravels therefore some one else may not have found them. Some one may have been always before me and picked them up, or I may have constantly looked over unproductive patches.

The places mentioned by Mr. Perceval are, it must be remembered, frequently ballasted with gravel brought from a distance by the Thames, by the Grand Junction Canal, and by the Great Western Railway. I know of at least five different localities whence the Acton and Hammersmith gravel is brought, one

[1] What I spoke of was "those problems in Probability which Boole justly regarded as the crowning triumph of his system." What Mr. MacColl puts between inverted commas is that Boole "justly regarded his problems in Probability as the crowning triumph of his system," and challenges me to say whether or not I agree with Boole's solution of a certain well-known example. This considerably distorts the meaning of what I said.

locality being in Kent. It is therefore of the highest importance that one should know for certain whence the gravel has been derived that one sees on the roads.

I live in an implementiferous district, and find Palæolithic implements in the Highbury and Clapton gravels; but a visitor would make a fatal mistake if he supposed that all the gravel on the roads about here belongs to the district. Sometimes many tons of gravel are brought here from Walthamstow; at other times from Ware or Hertford; sometimes from Dartford, and from other places. Unless, therefore, the greatest possible care is taken in ascertaining the exact locality whence the ballast comes, mistakes are certain to occur.

The lowest gravels about here are unproductive of the works of primæval man, with the exception of, at times, a stray flake or two, probably derived from a higher level. The evidence that I have seen in the lower gravels round London points to the correctness of the conjecture made by General Pitt-Rivers, that the Palæolithic age had passed away before the lower parts of the Thames Valley were excavated.

How to Prevent Drowning

I HAVE read with some interest Dr. MacCormac's letters on the subject of water-treading as means of preventing drowning.

I am sorry that I cannot agree with him, as it would be decidedly a matter of congratulation if some practical means of diminishing the number of casualties from drowning were found. Personal experience, however, prevents my agreeing with Dr. MacCormac.

I am a tolerably good swimmer, can swim in all the different fashions, but I can neither float nor tread water.

Shortly after Dr. MacCormac's first letter appeared I went to swimming baths with a view of putting the matter to the test. I had carefully read Dr. MacCormac's letter, and determined to give it a fair trial. I minutely observed all his directions, and invariably sank every time I tried his plan.

Now it must be remembered that I am a swimmer, and so far as swimming goes, perfectly at home in the water. Moreover, I was not in the least flustered. When I sank I made no attempt to rise again by swimming; I remained in what Dr. MacCormac would call the orthodox position for treading water, only opening my eyes in order to see whether I was ascending or descending. As however I found that I continued to do the latter until I reached the bottom of the bath, and there seemed to be no probability that I should rise without some further effort, I was at last compelled to make this effort.

This was the course of affairs every time I made the attempt. Moreover, whenever I essayed to float on the surface, although I carefully assumed the correct position, threw my head well back, and took the deep inspiration, the result was the same.

Arguing from these facts, it seems to me pretty clear that it is not everybody who can tread water or float. Why this is so, appears to me to lie in the fact that the human body is not always lighter, bulk for bulk, than water. Perhaps with plump children and others with plenty of adipose tissue about their frame this may be the case, but with spare people who consist mainly of muscle and bone, the specific gravity must be greater than that of water. The body of a fish when the animal is dead will sink until decomposition sets in and causes it to float.

For these reasons I fear that Dr. MacCormac's suggestion will not be found of so much practical use as he hopes. The apparent ease of the process described by Dr. MacCormac may in itself be the cause of rash proceedings by those who cannot swim, and may so lead to greater loss of life, the very evil which the suggestion is intended to diminish.

W. HENRY KESTEVEN

401, Holloway Road, N., June 7

ON the Continent the facilities are greater than in England, where factories and steam-boats spoil the pleasure of swimming, and everybody is well aware that *all can float upon fresh water without assistance from their hands and feet.* It is what in the Paris swimming-schools is called "faire le mort."

Anybody—stout, lean, cripple, halt—is able to do so, and I taught, myself, a poor little hunchback how to perform this easy feat; but his deformity placing him in a state of unstable equilibrium, he was obliged to keep his arms stretched at an angle from 45° to 60°.

Some minutes are sufficient in fresh water to make a proficient and a live "mort." The way to do it is very simple, and Mr. MacCormac described it very exactly, with the omission of some particulars relating to the way of breathing, which had no direct reference to his chief and beneficial topic, "treading water."

He who wishes to "faire le mort" must first draw a deep breath, and keep it, then put himself on his back, with his head thrown backwards, as recommended by Mr. MacCormac, and allow his limbs to droop slackly without any stiffness, no matter in what position.

The body will sink at first under water, but it will immediately rise nearly on a level with the surface, the only parts quite free from water being the chest and the nose and mouth, around which the water describes an oval, whilst the eyes are at times over, at times under, water.

The "mort" can remain floating in this way as long as his breath allows, though it is better not to wait longer than two or three seconds, to avoid fatigue; then he must quickly emit it, draw another deep breath, and keep it again.

The body sinks as before, rises immediately, regaining its floating position, nose, mouth, and chest emerging again from water.

This can be continued for hours together without the least motion of legs or arms, as your readers will be able to verify for themselves, either at the Pont Royal or Ligny swimming schools, on their visit to the Paris Exhibition of Electricity.

Jersey, June 5 CHATEL

P.S.—I ought to add that whilst floating on fresh water the body is not quite on a level with the surface, but from the chest, that is out of water, to the toes, which are about six or eight inches under water, figures an inclined plane, the slope of which varies with everybody, and that any attempt to bring the toes on a level with the surface makes the body sink. On the contrary, the deeper the head is sunk backwards under water the more the body emerges.

Auroric Light

JUNE 6, faint lights, especially to the northward, between 10 and 12; smart frost.

June 7, at 10, masses of purplish light rising from the north-east and congregating about the zenith; pencils of greenish yellow and white rising to the north; these continued up to 12, after which no observations were made; very smart frost, which bit the potato-stalks.

June 7, from 10 to 12, well-marked and at times brilliant columns, pencils, and masses of red rising all round the heavens at intervals, and congregating at the zenith; a most severe white frost that burnt up all the potatoes on the valley flats and on the uplands. At 5.30 on the 8th the frost was so thick that the ground had the appearance as if it had snowed during the night.

Ovoca, Ireland, June 10 G. H. KINAHAN

A Singular Cause of Shipwreck

IN NATURE, vol. xxiv. p. 106, you mention a "singular case of shipwreck" caused by waves and spray freezing on a steamer and sinking it by its weight. Cases of this kind caused by frozen spray alone are known near the east coast of the Black Sea. North of 44°, where the mountains are not very high, an exceedingly strong and sudden north-east wind is frequent, quite similar to the Dalmatian Bora, and called alike. It descends at a certain angle to the sea, raising a great quantity of spray. In winter this spray immediately freezes, and ships may sink by its weight. On January 25, 1848, a war-ship, anchored in the middle of the Bay of Noerrossiisk, sank in this manner. As the weather was fine before, a great part of the crew were ashore, and the storm arrived with such suddenness that the ship sank from the weight of the frozen spray. On account of the bora this coast is avoided by merchant-ships in winter, and visited only by a line of steamers subventioned by the Government.

St. Petersburg, June 8 A. WOEIKOF

OBSERVATIONS ON THE HABITS OF ANTS

ON Thursday (June 2) Sir John Lubbock read a further paper on this subject at the meeting of the Linnean Society. He said that in one of his former papers

(Linnean Soc. *Journ.* vol. xiv. p. 278) he had given a series of experiments made on ants with light of different colours, in order if possible to determine whether ants had the power of distinguishing colours. For this purpose he utilised the dread which ants, when in their nest, have of light. Not unnaturally, if a nest is uncovered, they think they are being attacked, and hasten to carry their young away to a darker, and, as they suppose, a safer place. He satisfied himself, by hundreds of experiments, that if he exposed to light the greater part of a nest, but left any part of it covered over, the young would certainly be conveyed to the dark portion. In this manner he satisfied himself that the different rays of the spectrum act on them in a different manner from that in which they affect us; for instance, that ants are specially sensitive to the violet rays. But he was anxious to go beyond this, and to attempt to determine how far their limits of vision agree with ours. We all know that if a ray of white light is passed through a prism, it is broken up into a beautiful band of colours—the spectrum. To our eyes it is bounded by red at the one end and violet at the other, the edge being sharply marked at the red end, but less abruptly at the violet. But a ray of light contains besides the rays visible to our eyes others which are called, though not with absolute correctness, heat rays and chemical rays. These, so far from being bounded by the limits of our vision, extend far beyond it, the heat rays at the red, the chemical rays at the violet end. He wished under these circumstances to determine if possible whether the limit of vision in the case of ants was the same as with us. This interesting problem he endeavoured to solve as follows:—If an ant's nest be disturbed the ants soon carry their grubs and chrysalises underground again to a place of safety. Sir John, availing himself of this habit, placed some ants with larvæ and pupæ between two plates of glass about one-eighth of an inch apart, a distance which leaves just room enough for the ants to move about freely. He found that if he covered over part of the glass with any opaque substance the young were always carried into the part thus darkened. He then tried placing over the nest different coloured glasses, and found that if he placed side by side a pale yellow glass and one of deep violet the young were always carried under the former, showing that though the light yellow was much more transparent to our eyes, it was, on the contrary, much less so to the ants. So far he had gone in experiments already recorded; but he now wished, as already mentioned, to go further, and test the effect upon them of the ultra-violet rays, which to us are invisible. For this purpose, among other experiments, he used sulphate of quinine and bisulphide of carbon, both of which transmit all the visible rays, and are therefore perfectly colourless and transparent to us, but which completely stop the ultra-violet rays. Over a part of one of his nests he placed flat-sided bottles containing the above-mentioned fluids, and over another part a piece of dark violet glass; in every case the larvæ were carried under the transparent liquids, and not under the violet glass. Again, he threw a spectrum into a similar nest, and found that if the ants had to choose between placing their young in the ultra-violet rays or in the red they preferred the latter. He infers therefore that the ants perceive the ultra-violet rays, which to our eyes are quite invisible.

Now as every ray of homogeneous light which we can perceive at all appears to us as a distinct colour, it seems probable that these ultra-violet rays must make themselves apparent to the ants as a distinct and separate colour (of which we can form no idea), but as unlike the rest as red is from yellow or green from violet. The question also arises whether white light to these insects would differ from our white light in containing this additional colour. At any rate, as few of the colours in nature are pure colours, but almost all arise from the combination of rays of different wave-lengths, and as in such cases the visible resultant would be composed not only of the rays which we see, but of these and the ultra-violet, it would appear that the colours of objects and the general aspect of nature must present to them a very different appearance from what it does to us.

Similar experiments which Sir John also made with some of the lower Crustacea point to the same conclusion, but the account of these he reserved for a future occasion. He then proceeded to describe some experiments made on the sense of direction possessed by ants, but it would not be easy to make these intelligible without figures. After detailing some further experiments on the power of recognising friends, he gave some facts which appear to show that ants by selection of food can produce either a queen or a worker at will from a given egg. Lastly he stated that he had still some ants which he had commenced to observe in 1874, and which are still living and in perfect health; they now therefore must be more than seven years old, being therefore by far the oldest insects on record.

THE WEATHER AND HEALTH OF LONDON[1]

TO the statistician London affords materials for the prosecution of many inquiries such as could not be obtained from the statistics of any other city either in ancient or modern times. Among the more important of these inquiries are those which relate to questions suggested by the enormous aggregation of human beings over a limited area which London presents on a scale absolutely unparalleled in the world's history. It is one of these questions we bring before you this evening, viz., the influence of the climate on the health of the people of London.

The relation of weather to health is a question which has engaged the attention of Dr. Arthur Mitchell and myself for many years. In an early stage of the inquiry our attention was mainly directed to Scotland, and more particularly to the data supplied by its eight large towns; but it was soon found that, owing to the sparseness and other conditions of the population, and to the fact that the division of time into months only, adopted by the Registrar-General for Scotland, they were not sufficiently minute to show the true relations of weather to the fluctuations of the death-rate through the year. In truth it was only after not a little unsuccessful labour, and what could at best be characterised as no more than partially successful work, that we resolved eight years ago to open the discussion of the whole subject by an exhaustive examination of the meteorological and vital statistics of London and London alone. More specifically our reasons for the selection of London were that it afforded data from (1) an enormous population spread over an area so limited that it might be regarded as having one uniform climate during each of the seasons of the year; (2) full weekly reports of weather and the deaths from the different diseases; and (3) returns extending over a sufficiently long period.

In the case of diseases such as diarrhœa and bronchitis, which seem to be directly and immediately under the influence of temperature, and such epidemics as scarlet fever and whooping cough, the rate of mortality from which is largely determined by season and weather, a comparatively small number of years is required to give a satisfactory approximation to their true weekly curve of mortality. But as regards the great majority of diseases, it quickly became apparent that a thirty years' average was required in the construction of curves which could be accepted as true "constants" for the diseases to which they refer. The thirty years beginning with 1845 were therefore adopted. An examination of the curves shows that some of their striking features, particularly those

[1] Substance of a Lecture delivered at the Royal Institution, March 25.

showing the complications of special diseases and their connections with each other, which the weekly averages disclose, would entirely disappear if monthly averages only were employed.

The curves of the more prominent and interesting of the diseases are shown on the accompanying woodcuts, the straight black line in each figure being drawn to represent the mean weekly death-rate on an average of the fifty-two weeks of the year, and the figures on the margin the percentages above or below the average. With this general average the mean death-rate of each week is compared and the difference above or below cal-

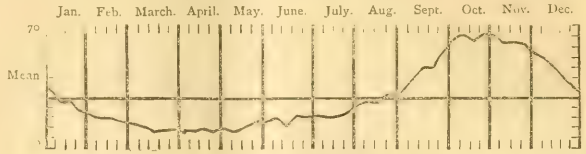

FIG. 1.—Scarlet Fever.

FIG. 2.—Whooping Cough.

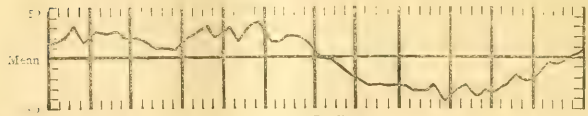

FIG. 3 —Small-pox.

culated in percentages, which, when *plus, are placed* above the mean line of the figure, and when *minus*, below it. Thus as regards scarlatina (Fig. 1), the mean of the fifty-two weeks is 49·6; on the first week of January it is 7 per cent. above the mean, from which time it continues to fall to the annual minimum, 35 per cent. below the mean in the middle of March, thence rises to the mean in the end of August; to the annual maximum, 60 per cent. above the mean, in the end of October, and thereafter steadily falls. The portion of the curve above the mean line thus shows the time of the year when, and the degree to which, the mortality. from scarlatina is above its average and the portion below the line when it is under it.

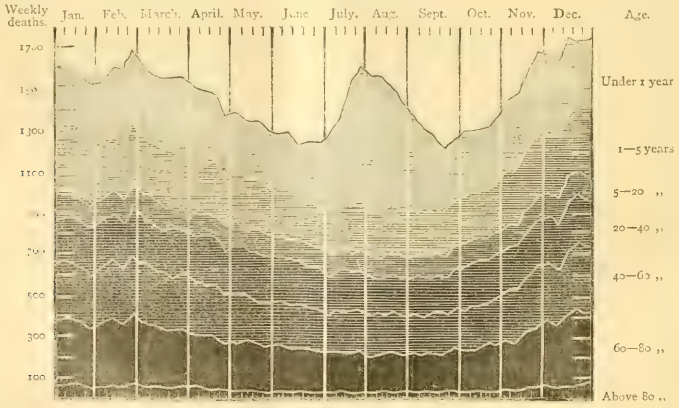

FIG. 4

Fig. 2 shows similarly the distribution of the mortality from whooping-cough through the weeks of the year, and Fig. 3 the distribution of the mortality from small-pox. It is seen at once that the mortality curve from scarlatina is precisely the reverse of the curve of whooping-cough, the maximum death-rate period of the one corresponding to the minimum period of the other, and *vice versâ*. It is also seen that the mortality curve for small-pox (Fig. 3) is quite distinct from the other two curves.

In order to ascertain the degree of steadiness of these curves, a curve was calculated and drawn for each of the seven epidemics of scarlatina and for each of the

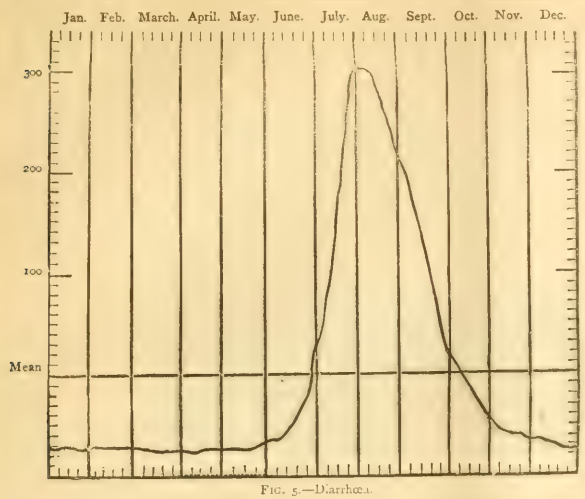

FIG. 5.—Diarrhœa.

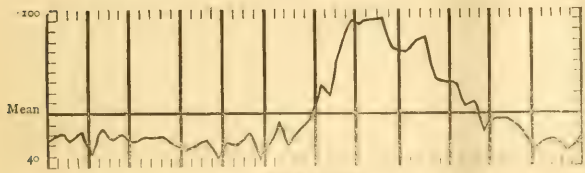

FIG. 6.—Thrush.

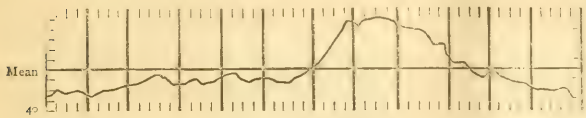

FIG. 7.—Tabes Mesenterica.

FIG. 8.—Enteritis.

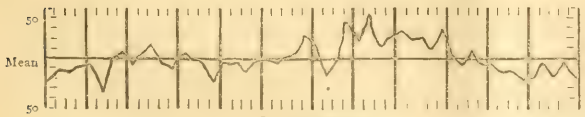

FIG. 9.—Jaundice.

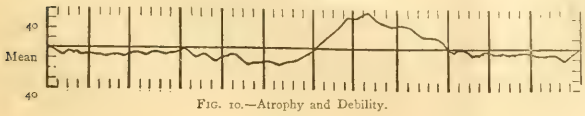

FIG. 10.—Atrophy and Debility.

eight epidemics of whooping-cough during the thirty years, with the instructive result that the curve for each of the separate epidemics was substantially identical with the general curve for the whole thirty years' period, each of the four prominent phases of each curve occurring all within a week of each other. As regards the small-pox curve, if the deaths during the epidemic of 1870-72, by far the most fatal of all the epidemics during the thirty years, be deducted from the general result, we obtain a curve which is substantially the same curve as that for the whole thirty years, but only less pronounced. From these results it follows, and the remark is of general application to all the curves, that the mortality curves for the different diseases arrived at in this inquiry may be regarded as true constants of these diseases for London.

The climate of London, looked at as influencing the health of the people, may be divided into six types of weather according to the season of the year. These are respectively—

Period 1.—Damp and cold, fourth week of October to third week of December.

Period 2.—Cold, fourth week of December to third week of February.

Period 2.—Dry and cold, fourth week of February to second week of April.

Period 4.—Dry and warm, third week of April to third week of June.

Period 5.—Heat, fourth week of June to first week of September.

Period 6.—Damp and warm, second week of September to third week of October.

The outstanding features of the death-rate in its relation to the varying types of weather through the year are shown by the top curve of Fig. 4, which represents the total mortality for all ages. This curve shows two maxima in the course of the year: the one, by far the larger of the two, extending over six months from November to April, and the other embracing the period from about the beginning of July to the autumnal equinox. It will be also observed that the comparatively short-continued but strongly-pronounced summer maximum is restricted to mere infants, whereas the larger winter maximum is a feature of the curves for all ages.

Figs. 5 to 10 are representative curves of those diseases which go to form the summer maximum when "*heat*" is the chief characteristic of the weather. The direct relation of the progress of mortality from diarrhœa to temperature is strikingly seen in the startling suddenness with which the curve shoots up during the hottest months of the year, and the suddenness, equally startling, with which it falls on the approach of colder weather. The curves for dysentery, British

cholera, and cholera are substantially the same as the curve for diarrhœa, all showing the same close obedience to temperature. It is a noteworthy circumstance that these four curves group themselves into pairs—diarrhœa and British cholera on the one side, and dysentery and Asiatic cholera on the other. The chief points of difference are that dysentery and Asiatic cholera begin markedly to rise considerably later than the other two allied diseases, attain their maximum a month later, and fall more rapidly than they rose, the annual phases being nearly a month later than those of diarrhœa and British cholera.

The peculiarly malignant character of summer diarrhœa among young children under five years of age may be shown by the weekly mortality from diarrhœa, rising from 20 in the middle of June, to 342 in the first week of August, 1880, when the mean temperature of July and August was about the average. In July, 1876, when the temperature was 3°·6 above the average, the weekly mortality from diarrhœa among children rose to 502 on the last week of that month. On the other hand, during the cold summer of 1860, the diarrhœa mortality for all ages did not in any week exceed ninety.

Of the British large towns the lowest mortality from summer diarrhœa is that of Aberdeen, which has the lowest summer temperature. The diarrhœa mortality of

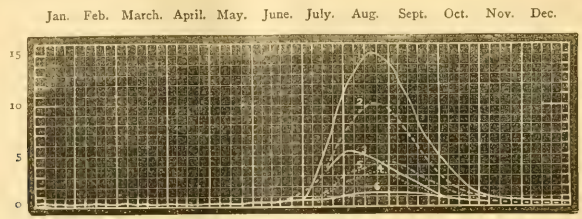

FIG. 11.—Weekly Deaths from Diarrhœa calculated on the Annual Mortality per 1000 of the population.

each town is found from year to year to rise proportionally with the increase of temperature, but the rate of increase differs greatly in different towns, thus pointing to other causes than mere weather, or the relative temperatures and humidities of these towns, as determining the mortality. Fig. 11 shows the weekly death-rate from diarrhœa for six of the large British towns, viz., Leicester, curve 1; Liverpool, 2; London, 3; Bristol, 4; Portsmouth, 5; and Edinburgh, 6; from which it is seen that though the summer temperature of London is hotter than that of Liverpool and Leicester, its diarrhœa mortality is very much less. In this respect London contrasts very favourably with the great majority of British large towns, showing its sanitary conditions generally are at least fairly satisfactory; but inasmuch as it is somewhat in excess of a few of the towns whose summer temperature is scarcely lower, London offers problems in this field to the sanitary reformer for his solution.

Figs. 6 to 10 give the curves for thrush, tabes mesenterica, enteritis, jaundice, and atrophy and debility, all of which have their maximum fatality during the hottest period of the year, and all of which, it will be noted, are bowel complaints. Indeed with the apparent exception of one or two nervous diseases, all those diseases which indicate an increase in their death-rate during the summer months are bowel complaints. ALEXANDER BUCHAN

(*To be continued.*)

NOTES

THE British Association having decided to hold its annual meeting this year at York, where, fifty years ago, its first meeting was held, it has been thought that advantage should be taken of this jubilee meeting to show, as far as possible, the progress which has been made during the past half century in the construction of instruments of scientific research, and, with this view, it has been decided to invite men of science, scientific societies, and manufacturers to exhibit, at the meeting, instruments of the latest patterns, and tools used in their construction; and if the science be fifty years old, the instruments used in 1831; otherwise specimens of the earliest patterns that can be found. The Exhibition will be for the week of the meeting only, viz. from August 31 to September 8. To ensure that specimens intrusted for exhibition shall be as advantageously placed as possible, a special sub-committee, called "The Museum Sub-Committee," has been formed at York, who will be happy to afford every possible information. The sub-committee includes several gentlemen who have had considerable experience in the arrangement of exhibitions, and they will give their personal attention to the unpacking, arrangement, and care of objects intrusted to them, so that the risk of injury will be reduced to a minimum. The articles exhibited will be insured against fire, and provision will be made for police protection; beyond this the committee does not hold itself responsible. It is requested that exhibitors will put a value on their exhibits, in order that the necessary insurance may be made. The proposed Exhibition will also include apparatus and specimens illustrative of papers to be read at the Association meeting, which the authors may be willing to allow to be examined at leisure, as well as instruments constructed for the prosecution of special researches which have not yet become articles of ordinary commerce. It is very desirable that such instruments and apparatus should be exhibited in action, if arrangements can be made for the purpose.

THE thirtieth meeting of the American Association for the Advancement of Science will be held at Cincinnati, Ohio, commencing on Wednesday, August 17, and following days. As it is generally believed that the Cincinnati meeting will be the largest and most important scientific meeting ever held in the West, every effort will be made by the Local Committee to prepare, in advance of the meeting, a satisfactory general programme for the week. At the Boston meeting several changes in the constitution were proposed, which will come up for action at Cincinnati, the object of the changes being the reorganisation of the sections, and also to extend the scope of the Association. Should these changes be adopted, the Association will embrace eight sections of equal standing, each presided over by a vice-president, and having its own secretary and sectional committee. The following is the division proposed, and upon which final action will be taken at Cincinnati:—Sec. A. Physics; Sec. B. Astronomy and Pure Mathematics; Sec. C. Chemistry, including its applications to Agriculture and the Arts; Sec. D. Mechani-

cal Science; Sec. E. Geology and Geography; Sec. F. Biology; Sec. G. Anthropology; Sec. H. Economic Science and Statistics. Also I. A Permanent Subsection of Microscopy, which shall elect its own officers and be responsible directly to the Standing Committee. Several excursions will be arranged for by the Local Committee, and will be announced on their circular. Special excursions will be arranged for the Anthropological Section to Fort Ancient, Madisonville, and other places of interest. The Permanent Secretary of the Association is Prof. F. W. Putnam, Salem, Mass.

THE Paris Academy of Sciences elected, on June 13, M. Fouqué, Professor of Mineralogy to the Collége de France, a Member of the Section of Mineralogy, to fill the seat vacated by the death of M. Delesse.

AT the first General Meeting of the Members and the Honorary Council of the Sanitary Assurance Association on Friday last, Prof. Corfield (Chief Sanitary Officer) and Mr. Judge (Surveyor) related to the meeting the progress of the Association, and reported on the work of sanitary inspection that had been done. The property which had been placed on the Assurance Register varied in value from houses rated at 60*l.* a year, in which the total fee to subscribers for report, supervision of work, and certificate, is two guineas, to houses rated as high as 700*l.* a year, with proportionately increased fees. The Association undertakes the inspection of the smallest class of property, and no fee is charged to subscribers for a single house rated at 20*l.*, while the fee is only half a guinea for houses rated at 40*l.* In the discussion which followed, Sir Richard Temple, Capt. Douglas Galton, and Mr. Whichcord spoke strongly in support of the objects of the Association, and the Council were requested to take steps to make the Association as widely known as possible, and particularly to call the attention of the proprietors of large building estates to the advantages which would accrue if the certificate of the Association was made essential to the granting of leases.

THE prize programme of the Belgian Academy of Sciences for 1882 consists of the following subjects (briefly stated):—Distribution between acids and bases, in mixture of solutions of salts which, by their mutual reaction, do not produce insoluble substances; *exposé* of present knowledge of torsion and improvement of it; extension of knowledge of the relations between the physical and chemical properties of simple and compound bodies; description of Belgian Tertiary strata of the Eocene series; influence of the nervous system on regulation of temperature in warm-blooded animals; relations of the pollinic tube to the ovum in one or more Phanerogams. Medals of the value of 600 francs are offered in connection with each question, except the third, for which the medal is valued at 1000 francs. The time-limit is August 1. For 1883 the following three questions are adopted:—1. Establish by new experiments the theory of reactions presented by substances in the nascent state. 2. Prove the truth or falsity of Fermat's proposition: To decompose a cube into two other cubes, a fourth power, and generally any power, into two powers of the same name, above the second power, is impossible. 3. New spectroscopic researches are required, showing especially whether or not the sun contains the essential constituents of organic compounds. A gold medal of 800 francs value is offered for solution of any one of these. The time-limit is August 1, 1883. Memoirs must be written in French, Dutch, or Latin, and sent in with motto and sealed envelope to the secretary.

WE learn that M. Planté, the inventor of the electrical accumulator, intends to organise a factory for the sale of his instruments. M. Planté considers himself obliged to take this step in order to show that the principles of his original apparatus are sufficient to work them with advantage. It appears that the Faure accumulators with oxide of lead cannot be loaded except by a battery, and that the original lead can be worked by a magneto-electric machine, by taking some precautions which will be described shortly. M. Plante is constructing for M. Tissandier an accumulator on his original system, which will be used to direct a small elongated balloon. It is intended to exhibit it in the nave of the Palais de l'Industrie in August next.

OUR Paris Correspondent writes: On June 10 an interesting experiment took place in Paris. A little after midnight a tram-car belonging to the Omnibus Company conveyed forty persons from the Place du Trone to the Boulevard Richard Lenoir and back at a velocity of six miles an hour. The motive power was supplied by 160 Faure accumulators, weighing 18 lbs. each. An interesting feat was accomplished, but not quite such as was anticipated. The work could have been done by two horses. The experiment lasted about one hour, and the power of the motor, although not exhausted, was much diminished.

M. JOSÉ CUSTODIO, Marinha Grande, Leiria, Portugal, writes to say that the centenary of the death of the great Portuguese Minister, the Marquis of Pombal, is to be celebrated on May 8 of next year. In connection therewith it is desired to obtain information about Williams Stephens, who founded the first royal manufactory of glass in Portugal, under the patronage of Pombal. Any information whatever concerning Stephens will be welcomed.

WE would draw the attention of our readers to the announcement of the first general meeting of the Society of Chemical Industry on the 28th and 29th inst., at the Institution of Civil Engineers, with Prof. Roscoe in the chair.

THE Portfolio of Drawings of Living Animals and Plants issued by Mr. Thomas Bolton for June, 1881, is a very creditable production, and we are glad to call our readers' attention to the opportunity there is afforded to them by the labours of Mr. Bolton, of investigating fresh and living specimens of very many interesting forms of animal and vegetable life—for the most part of quite microscopical size—and at the same time of having, by the drawings which accompany these forms, an excellent sketch of what they are to expect to find, and a short but authentic history of what is known about them.

M. MASCART, the director of the French Meteorological Service, is devising a new registering magnetometer, which is intended to have all the indications recorded on one roll of paper.

AN earthquake shock was felt in Switzerland on Thursday morning last. The shock occurred at 12.35 a.m. The direction was south-west to north-east at Geneva, and north-east to to south-west at Lausanne, Martigny, and Bex. Prof. Morel of Morges describes it as having been for one region very intense; it was felt from Martigny and Bex, in the Valais, to the valley of Joux, in Vaud; at Geneva, Chamounix, and all round Lake Leman. Its centre was probably in the valley of the Upper Rhone, where seven or eight oscillations were distinctly perceived, accompanied in many places by subterranean thunder, bells were rung, walls cracked, slates dislodged, and chimneys overturned. It was also felt at Osmondo, notwithstanding the great height of the village above sea-level. A second shock was felt some hours later in the same locality.

INTELLIGENCE received at Constantinople on June 9 from Van states that an earthquake has devastated thirty-four villages in that district. Another shock of earthquake occurred at Chios at half-past nine on Saturday morning, causing the fall of a Turkish minaret and of several ruined houses in the town. Oscillations of the ground are constantly noticed in Croatia. Thus on May 19 at 2 a.m. a violent shock, lasting three seconds, and accompanied by subterranean noise, was observed at Glina.

The shock was felt at Agram also, and at several other Croatian towns. On May 23, at 8.21 p.m., an earthquake was observed at Metkovich (Dalmatia). It lasted eight seconds, its motion was wave-like, and in a south-westerly direction; at 9.45 p.m. a second one followed. At Janina no less than seven different shocks were noticed on the same day; they varied considerably in strength, the first one occurred at 10.15 a.m., the last one at 10.57 p.m. All were accompanied by subterranean noise. At Stagno two violent shocks occurred at 8.23 and 9.3 p.m., and at Slano a moderate one at 8.35 p.m. On May 22 at 6.15 p.m. an oscillation of the ground was observed at Zwickau (Saxony); the direction was from north-east to south-west. On May 21 a moderate shock was noted about 11 p.m. at Copenhagen and in the vicinity. It lasted six seconds.

Mr. W. Sowerby, writing from the Botanical Gardens to the *Times*, states that the fresh-water jelly-fish described in Nature a year ago by Professors Allman and Ray Lankester, has reappeared in the Victoria Regia tank in the Gardens. It is a curious fact that the date of its first discovery (June 9, 1880) should be so near the day of its reappearance—viz. June 12; as during the winter the tank is cleaned out and remains for some months empty.

The numbers of the present year's issue of our northern namesake, *Naturen*, under the recent editorship of the eminent Norwegian geologist, Hans F. Reusch, continue to provide well written popular expositions of scientific questions. Dr. Leonhard Stejneger returning to a subject which he had treated of in early numbers, considers the causes which influence the migration of birds, which he is disposed to seek principally in the necessity originally imposed on earlier generations to seek food by change of locality, when the cold in one region, and the heat in another, destroyed the smaller animals, or the plants, from which these birds sought their nourishment, while the sense once developed became in process of time an hereditary instinct. The editor describes the working of the telephone system in Christiania, where, since June, 1880, a central station, in which the work is done by women, has been established in connection with Dr. Bell's Company in New York, and under the direction of Herr Hugo Ullitz. The apparatus used is the so-called Blake's microphone. Herr Geelmuyden draws attention to the expediency of adopting one mean time, viz., that of Christiania, for all Norway. The difficulty of establishing one normal time for the whole country is especially great in Norway, where, for instance, some districts—as Vardö and Vadsö—lie further east than Constantinople, while the west coast has nearly the same W. long. as Marseilles. As one of the curious results that would follow the adoption of the time of Christiania as the normal standard he mentions that the midnight sun at the North Cape would have to be looked for at 11 P.M. A colossal pine which was lately uprooted by an inundation at Pyhajoki in Oulais, Finland, was found to have 1029 annual rings. The Norwegian Arctic Expedition has yielded a new fish bearing affinity with the Ophidiidæ, but presenting sufficient differences to justify its recognition as a hitherto unknown northern form, for which Dr. R. Collett has suggested the name *Rhodichthys regina*. The entire yield of fish in the trawl-nets at great depths (from 1300 to 1400 fathoms) was 234 individuals, belonging to thirty-two different genera, of which seven had been previously unknown to science.

The deaths are announced of Dr. Jakob Bernays, Principal Librarian at the Bonn University, and of Dr. Richard Ladislaus Heschl, Professor of Pathological Anatomy at the University of Vienna (the successor of Rokitanski). Both were fifty-seven years of age, and both died on May 26.

The Highbury Microscopical and Scientific Society gave a *conversazione* at Harecourt Hall, Canonbury, on Thursday, the 9th inst., which was numerously attended.

There is a regular mania in Paris at present for publishing periodicals connected with electricity. A new electrical weekly paper called the *Telephone* has issued its first number; it is the fifth in existence. We are told moreover that the first number of another, the *Electrophone*, will be issued in a very few days.

Mr. Henry Walker has issued a useful little "Guide to the Popular Natural History Societies of London." In London and suburbs there are twenty such associations.

The *conversazione* to commemorate the fiftieth anniversary of the Harveian Society of London will be held on Wednesday, June 29, at the South Kensington Museum.

Experiments have been made during the past few days in lighting the House of Commons by means of the electric light.

Seven solar lamps were lighted by electricity about a week ago in Paris by a Siemens machine, situated in the *mairie* of rue Drouat. These lamps, which are perfectly regular, and placed in the most crowded part of the Paris Boulevards, near Passage Jauffroy, have created a sensation.

The concerts of the Palais Royal will be resumed in a few days. The gardens will be lighted by no less than eighteen Jablockhoff lamps. It is intended to place a miniature electric boat on the basin manned by a little girl.

The annual Congress in connection with the French Society of Archæology will be opened on June 28 at Vannes (Morbihan). A long and interesting programme has been prepared for the meeting.

The additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius*) from South Africa, presented by Miss Agnes Robertson; a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. Hamilton Kerr; a Malbrouck Monkey (*Cercopithecus cynosurus*) from West Africa, presented by Mr. H. Aylesbury, steam yacht *Albion*; a Common Ocelot (*Felis pardalis*) from America, presented by Mr. P. Leckie; two Common Peafowls (*Pavo cristatus*) from India, presented by Mr. George Stevenson; a Lesser Sulphur-crested Cockatoo (*Cacatua sulphurea*) from the Moluccas, presented by Miss Rose Hubbard; three Waxwings (*Ampelis garrulus*), European, purchased; a Cape Buffalo (*Bubalus caffer*), a Japanese Deer (*Cervus sika*), born in the Gardens; nine Summer Ducks (*Aix sponsa*), a Jameson's Gull (*Larus jamesoni*), bred in the Gardens.

GEOGRAPHICAL NOTES

At its last meeting the Russian Geographical Society announced the nomination of M. Yurgens as Director of the Polar Meteorological Station on the Lena, and of M. Eichner and Dr. Bunge as his assistants. The Society also voted sums of money for sending M. Kouznetsoff for the anthropological exploration of Tartarian tribes and for M. Malakhoff, who goes to the provinces of Vyatra and Oufa for the exploration of caverns and of remains of former settlements.

We find in the *Izvestia* of the Russian Geographical Society the following information as to the geodetical work which was done by the Russian officers on the Balkan peninsula during the last war. The whole of Bulgaria and Eastern Roumelia was covered with a net of trigonometrical triangles, as well as the portion of Turkey between Adrianople, Dede-agatch, and Rodosto, and from Yambol, through Adrianople, to Constantinople and Bourgas. The net goes also into Servia and along the Danube, the total number of geodetically-determined spots being 1289; for all these spots there were also made determinations of heights. The highest determined summits on the Balkan mountains are Youmroutchkal (7791 feet), and Vajan (6217 feet); and in the Rhodope Mountains: Karlyk (9846 feet), Karlyk-moolah and Sutka (both 7189 feet high). The longitudes of eleven principal towns (Rouschouk, Sistova, Tirnova, &c.) were determined with great accuracy, and those of fifty-seven others either by telegraph or by chronometers, and

they were chosen in such a manner as to determine the influence of the Balkan chain on the deviation of the pendulum. As to the topographical work, no less than 133,750 square versts were mapped during the war, of which 110,500 square versts were mapped on the scale of $\frac{1}{126000}$, and the heights of more than 110,000 spots were determined, so that there are all necessary data for making an embossment-map of the whole of the mapped parts of Roumelia and Bulgaria.

DR. RAE sends us the following extract from a letter to him from Capt. Howgate, dated May 23, 1881:—"Our Arctic work here is progressing finely, so far as our fitting is concerned. The *Jeannette* search vessel is to get off early in June, if she fills up her complement of men. For our Lady Franklin Bay work the steam sealer *Proteus* of St. John's, Newfoundland, has been secured. She is a vessel of 688 tons burden, and contracts to deliver, with the colony and supplies, one hundred tons of coals at Lady Franklin Bay, which will guard against failure in the item of fuel, should the coal-seam not turn out so well as expected. The complement of men has been made up, and the shipment of stores to St. John's actually commenced, so there is every reason to expect that the expedition will sail from that port on July 4, as originally intended. The Point Barrow party is nearly filled up, and will be finished this week, I believe."

A SHORT time back it was stated that Mr. James Stevenson of Glasgow had offered to contribute 4000*l.* on certain conditions for the construction of a road between Lakes Nyassa and Tanganyika. The Foreign Missions Committee of the Free Church of Scotland have resolved to do their part by establishing a station among the Chungus at Maliwanda, a place about fifty miles on the proposed line of road from Lake Nyassa. The London Missionary Society have agreed to open a station at Zombé, twenty miles to the south-east of Lake Tanganyika. In order to found the Livingstonia Mission's new stations and superintend the construction of the road, Mr. James Stewart, C.E., left England on May 13 with three artisans, and another is to follow. In the autumn also it is probable that another medical missionary will go out to Lake Nyassa.

BY the aid of a correspondent at the Gaboon who wrote on March 30 a contemporary has received the startling intelligence that M. de Brazza "got to Stanley's Pool from the Ogowé and came down the Congo." Some people however may be aware that this information was made public at the meeting of the French Geographical Society on January 21, when M. Duveyrier tried to make quite clear what is evidently not yet known at the Gaboon, viz. that after he had founded the Ogowé and Stanley Pool stations and descended the Congo, the mission confided to M. de Brazza by the French branch of the International African Association ceased, and the two stations, it is well known, are to be taken charge of by M. Mizon and another Frenchman. M. de Brazza is now engaged on an expedition for which the French Chambers have made a liberal grant, and in which he will be accompanied by his former colleague, Dr. Ballay. These two are to descend the Alima to the Congo in a steam launch, and then to make a thorough examination of the valley of the great river, part of their object being to divert trade to some extent to the Ogowé. The writer of the letter from the Gaboon believes that "Stanley will find de Brazza established there [? Stanley Pool] when he gets up." This of course is a matter of chance, as M. de Brazza has now a sort of roving commission on the Congo, but, no doubt, Mr. Stanley will find some one at the Ntamo station (now called Brazzaville), as Messrs. Crudgington and Bentley in February found a French sergeant and two soldiers there, and by this time possibly M. Mizon or some one else will have arrived to take charge.

IN consequence of the success of the preliminary journey which Mr. Crudgington and his companion have just made along the north bank of the Congo to Stanley Pool, the Baptist Missionary Expedition will now definitely adopt this route into the interior. As the result of a long conversation with Mr. Stanley on the subject, the party consider that it will be best to take advantage of his road as far as Isangila, and then to place a steel boat on the river above the falls there. Afterwards there will be no insuperable difficulty in the navigation of the river, except perhaps in two or three places where the boat will be taken to pieces and carried past the cataracts. A boat is now being built for the expedition in London from the plans and drawings of Mr. Stanley, who has willingly afforded the party the benefit of his advice and assistance. The adoption of this plan will obviate the necessity for passing through the country of the troublesome Basundi, and will materially hasten the progress of the expedition.

HERR ERNST VON HESSE WARTEGG, the well-known traveller, has just returned to Europe from Africa, where he went up the Nile, and then crossed the desert between that river and the Red Sea, making important excavations and discoveries of ancient Egyptian remains, among which were a very interesting sarcophagus, pottery, statuary, &c. He recently gave a lecture before the Geographical Society of Alsace-Loraine at Metz, exhibiting several hundred photographs and ethnographical objects. Some time ago Herr von Hesse Wartegg was elected Honorary Member of the Royal Belgian Geographical Society and Corresponding Member of the Geographical Society of Metz. His travelling companion, Dr. Theodor Hoerner, has gone from Suakin to Kassalla, and from there through the Kunama country to Massawah.

IN the *Colonies and India* we find some particulars respecting a projected expedition from New Zealand to New Guinea for the purpose of exploration and eventual colonisation. The promoters two years ago made a preliminary voyage there in the *Courier*, which for various reasons was not particularly fortunate, but from their past experience they now feel certain of success. The *Courier* then visited Astrolabe Gulf, on the north-east coast, and the natives were found very tractable and disposed to trade. Scented woods were met with in abundance, and tobacco and sugar were seen under cultivation. Mr. R. Mills, who was with this expedition, has brought away with him numerous views taken on the spot, which give a good idea of the natives and the aspect of the country.

LETTERS have been received at Vienna from the African traveller, John Freiherr von Müller. He intends to penetrate into the district south of Fazoglu and Fadazi, which hitherto have never been visited by any European. The geographical problems to be solved in these parts are the discovery of the bifurcation of the Sobat River (a tributary on the right bank of the White Nile), which was suspected by Karl Ritter, and also the discovery of the problematical Zamburu and Baringo lakes. The general circumstances in these districts do not justify the hope of success being oversanguine; yet Freiherr von Müller hopes safely to reach the Indian Ocean at Mombassa or Bagamoyo on his return journey.

ON Monday last week Dr. Ave-Lallemant delivered a lecture to the members of the German Athenæum, Mortimer Street, on the Orinocco River. The lecturer spoke mainly from personal observation, and the lecture was a highly interesting one.

A GENERAL Congress of German geographers, presided over by Dr. Nachtigal, met in Berlin last week. The second volume of Dr. Nachtigal's work on the Sahara and Sudan is expected shortly.

LIEUT. BOVE has just returned from the Argentine Republic, where he has been making arrangements for the projected expedition to the Antarctic regions. The Geographical Institute of the Argentine Republic has unanimously voted 2000 scudi for the enterprise. As soon as the Italian Government has arranged the diplomatic affairs of the expedition with the Argentine Republic, Lieut. Bove will return to Buenos Ayres.

HEFT VI. of *Petermann's Mittheilungen* commences with an interesting article on the Greatest Quantity of Rainfall in One Day, by Dr. H. Ziemer. Letters from Dr. Junker give interesting details concerning his sojourn in the Niam-Niam country, and an article, with map, on East Griqua Land and Pondo Land brings together recent information on these regions. Another article gives the leading results of some recent journeys in Arabia.

NO. 4 of the *Mittheilungen* of the Vienna Geographical Society contains an account, by Dr. Emin Bey, of his journeys in the Upper Nile Region; and Joh. Ritter Stef. v. Vilnovo has a long paper on the side-courses of rivers. In No. 5 Dr. Holub has a useful paper on the industrial aspect of Austrian exploration; Dr. Jettel writes on the scientific exploration of Bosnia and Herzegovina; and Lieut. Kreitner on the Ainos.

THE murder is reported of an Italian exploring party in the Danakil country. According to the latest advices from Aden, the party was composed of the traveller Giulietti, and an escort furnished by the commander of the vessel stationed at Assab. The party, whose object is stated to have been scientific and

commercial, left Beilul last April to explore the source of the Gualima. Four days distance from that town they were attacked and slain by the natives. Signor Giulietti was well known for the difficult journey he accomplished from Zeila Hazar. He was asked by the Geographical Society to explore the interior of the west coast of the Red Sea. At first a journey to Lake Aussa was contemplated, but obstacles arising, the plan was changed for an expedition into the Assab Gallas country.

AT the meeting of the Geographical Society on Monday last Capt. W. J. Gill, R.E., read some extracts from a long account of his explorations in Western Szechuen, which has lately been sent home by Mr. E. Colborne Baber, now Chinese Secretary of H.M. Legation at Peking. The extracts chosen dealt chiefly with the amusing side of Mr. Baber's journey, but the paper, nevertheless, contains abundance of solid information respecting the extreme west of China, and, as Lord Aberdare stated in his anniversary address, is considered by competent judges to be a noteworthy contribution to our knowledge of Asiatic geography. The most valuable part of the extracts read is probably that respecting the almost unknown Lolo country, in the neighbourhood of Ning-yüan-fu. Mr. Baber sent home copies of some pages of a Lolo manuscript, no specimen of which, we believe, has ever been seen in Europe before. These have been submitted to the well-known scholar, M. Terrien de la Couperie, who gave the meeting a brief account of the results of his examination of them. Mr. Baber's paper will be published by the Society, together with the valuable cartographical matter which accompanied it.

M. AND MADAME UJFALVY were to leave Simla for Kashmir, *viâ* Kangra, on June 6. From Kashmir they hope to penetrate into Thibet and Central Asia.

THE death is announced of Mr. Andrew Wilson, author of a well-known book of travel in the Himalayas, "The Abode of Snow."

SOLAR PHYSICS—CONNEXION BETWEEN SOLAR AND TERRESTRIAL PHENOMENA[1]

II.

IN my last Lecture I alluded to the complicated periodicity which sun-spots exhibit. It is right here to quote the remark of Prof. Stokes, that until we have applied to solar phenomena a sufficiently rigid analysis we are not certain that this apparent periodicity will bear all the marks of a true periodicity. It cannot however be denied that solar phenomena are roughly periodical, and this apparent periodicity has influenced observers in their attempts to search for a cause. There have been two schools of speculators in this interesting region, consisting of those who imagine a cause within the sun, and of those who imagine one without. The former *may* be right, but apparently they cannot advance our knowledge much. We know very little of the interior of the sun, and no one has yet ventured on any hypothesis regarding the *modus operandi* by which these strangely complicated and roughly periodical surface phenomena may be supposed to be produced by the internal action of the sun itself.

Those who maintain the hypothesis of an internal cause are apparently driven to it by the *à priori* unlikelihood of any cause operating from without. No doubt we have around the sun bodies, the motions of which are strictly periodical, such as planets, comets, and meteors, but they are relatively so small and so distant, that it seems difficult to regard them as capable of producing such vast phenomena as sun-spots.

There is however this difference between the two hypotheses—those who assert internal action cannot convert their views into a working hypothesis. On the other hand, those who look to external sources can take the most prominent planets, for instance, and endeavour to ascertain whether as a matter of fact the behaviour of the sun with regard to spots is apparently influenced by the relative positions of these. Attempts of this nature have been made by Wolf, Fritz, Loomis, Messrs. De La Rue, Stewart, and Loewy, and others. These attempts have been of two kinds. In the first place observers have tried whether there appear to be solar periods exactly coinciding with certain well-known planetary periods. By this means the following results have been obtained by the Kew observers (Messrs. De La Rue, Stewart, and Loewy):—

(1) An apparent maximum and minimum of spot energy approximately corresponding in time to the perihelion and aphelion of Mercury.

(2) An apparent maximum and minimum of spot energy approximately corresponding in time to the conjunction and opposition of Mercury and Jupiter.

(3) An apparent maximum and minimum of spot energy approximately corresponding in time to the conjunction and opposition of Venus and Jupiter.

(4) An apparent maximum and minimum of spot energy approximately corresponding in time to the conjunction and opposition of Venus and Mercury.

Mr. De La Rue and his colleagues make the following remarks upon these results:—

"There appears to be a certain amount of likeness between the march of the numbers in the four periods which we have investigated, but we desire to record this rather as a result brought out by a certain specified method of treating the material at our disposal, than as a fact from which we are at present prepared to draw conclusions. As the investigation of these and similar phenomena proceeds it may be hoped that much light will be thrown upon the causes of sun-spot periodicity."

I may here mention that within the last month I have, in conjunction with Mr. Dodgson, applied a method of detecting unknown inequalities with the view of seeing whether there are any indications of an unknown inequality in sun-spots having a period near that of Mercury, and I find there are indications of such an inequality having a period which does not differ from that of Mercury by more than about three-hundredths of a day. Besides the four periods above mentioned the Kew observers have, they think, detected evidence of a periodicity in the behaviour of spots with regard to increase or diminution depending apparently on the positions of the two nearer planets, Mercury and Venus. The law appears to be, that as a portion of the sun's surface is carried by rotation nearer to one of these two influential planets, there is a tendency for spots to become less and disappear, while on the other hand when it is carried away from the neighbourhood of one of these planets there is a tendency for spots to break out and increase.

The Kew observers regard this latter species of evidence as being well worthy of a more exhaustive discussion when the sun-spot records are more complete. I have already mentioned that the chief difficulty in attributing solar outbreaks to configurations of the planets is the comparative smallness and great distance of these bodies, so that when we reflect on the enormous amount of energy displayed in a sun-spot we cannot but have great difficulty in supposing that such vast phenomena can be caused by a planet like Venus, for instance, that is never as near to the sun as she is to the earth. But this difficulty depends very much on what we mean by the word "cause." If we mean that the planets cause sun-spots in the way in which the blow of a cannon-ball or the explosion of a shell causes a rent in a fortification, the hypothesis is certainly absurd. But if we only mean that the planets act the part of the man who pulls the trigger of the gun, the hypothesis may be unproved, but it is no longer absurd. For we have reason to believe that there may be great delicacy of construction in the sun's atmosphere, in virtue of which a small cause of this kind may produce a very great effect.

We may therefore believe it possible that planets may act in this way on the sun—the energy displayed in a spot being however not derived from the planets, but from the sun itself, just as the energy of a cannon-ball is not derived from the man who pulls the trigger, but from the explosion in the gun.

All this is chiefly historical, and it leads to a very interesting query. If there is such an action of a planet on the sun, must not this have a reaction? If the earth influences the sun, must not the sun simultaneously influence the earth? Perhaps so; nevertheless it is not an influence of this kind which I shall now bring before you. The sun is periodically stirred up—no matter how—and being stirred up there is an increase in the light and heat which are radiated to the earth. This affects the meteorology of the earth, and also its magnetism, after a method which, if we do not fully understand it now, we may ultimately expect to comprehend. It is this kind of influence, and not an occult action, of which I shall now bring the evidence before you

[1] Lecture in the Course on Solar Physics at South Kensington; delivered by Prof. Balfour Stewart, F.R.S., April 27. Continued from p. 117.

And first of all let me speak of the sun's influence on the magnetism of the earth.

Suppose that the chief observatories of the world have each a vault, and that in this vault a magnetic needle is delicately suspended. We may imagine the sun to be shut out altogether, the only light being that of a lamp which enables us to record, either photographically or otherwise, on a magnified scale any small oscillations of the needle. The vault may be supposed to be sufficiently deep down to be practically uninfluenced by the heat of the sun, so that it will exhibit no difference in temperature between noon and midnight. Finally there must be no iron or steel about the place, or anything which might affect the needle. Now under these circumstances you would naturally imagine that the needle would be perfectly stationary, always pointing in the same direction. Such, however, is not the case—it does not move very greatly, but nevertheless it does move, and its position depends on the hour of the day, or, in other words, upon the sun. The sun cannot heat the chamber in the least, nevertheless it can influence the magnet, and we might even tell in a rough way the hour of the day by noting the position of the needle. In this country the needle attains one extreme in its daily progress about five or six in the morning, and the other about one or two in the afternoon, and the difference in position of these two extremes is called the diurnal range of magnetic declination. Here then we have a magnetical phenomenon which depends upon the sun, and which does not take place simultaneously at the various observatories of the earth, inasmuch as the sun travels from east to west, so that when it is six in the morning at one place it may be midnight at another.

In the next place, we have abrupt magnetical changes analogous to the well-known abrupt meteorological changes, and bearing the appropriate name of magnetic storms.

A magnetic storm is not a mere local outbreak, but is felt simultaneously at all the various points of the earth's surface. The various needles in the various vaults of which we have now been speaking will all be affected at the same moment of time, and will be found to be oscillating backwards and forwards in a disturbed state. It thus appears that diurnal ranges and magnetic storms are two distinct phenomena.

To begin with diurnal declination ranges. These have, as their very name implies, a connexion with the hour of the day, and hence with the position of the sun. Again, in middle latitudes declination ranges are greatest in summer when the sun is most powerful, and least in winter. Lamont was the first to observe the signs of a long period inequality in the yearly means of the Munich diurnal declination ranges, and in 1852 Sir Edward Sabine succeeded in showing that this inequality followed that of sun-spots previously discovered by Schwabe, maximum ranges corresponding to years of maximum sun-spots, and minimum ranges to years of minimum sun-spots. In the same year Dr. Wolf and M. Gautier independently remarked the same coincidence.

But there is more than a mere general correspondence between these two phenomena, for it is believed that all inequalities of sun-spots, whether of long or short period, are accompanied by corresponding changes of declination range, a large range invariably accompanying a large number of spots. Perhaps I ought to say a large range following a large outbreak of spots, for the solar phenomenon leads the way and the magnetic change follows after it at a greater or less interval of time. I may add, likewise, that we have some evidence which leads us to suspect that particular states of declination range, like particular states of weather, have a motion from west to east, the magnetical weather moving faster than the meteorological. From a preliminary investigation which I have made, I even think there may ultimately be a possibility of forecasting meteorological weather by means of magnetic weather five or six days before. It will be noticed, that as far as declination range is concerned, we have no evidence of a direct magnetic action of the sun upon the earth, but we have, on the other hand, evidence that the magnetic effect, like the meteorological, lags behind the cause in such a way that we are inclined to attribute the magnetic as well as the meteorological phenomena to the heating effect of the sun's rays.

Let us next take magnetic storms. These, as we have seen, affect the various stations simultaneously, so that the magnetism of the earth appears to change as a whole, and in this respect they are very different from the ordinary diurnal oscillations of the needle. Nevertheless, equally with declination ranges, magnetic storms appear to depend on the state of the sun. In 1852 Sir Edward Sabine showed that in those years when there are most sun-spots there are most magnetic storms, while, on the other hand, years of minimum sun-spots correspond to a minimum number of such storms. The late John Allan Broun, an eminent magnetician, has given reasons for believing that the greater magnetic disturbances are apparently due to actions proceeding from particular meridians of the sun; this when verified will be a fact of the greatest importance.

Again, Prof. Loomis of America, from a discussion of 135 cases of magnetic disturbance, concludes that great disturbances of the earth's magnetism are accompanied by unusual disturbances of the sun's surface on the very day of the magnetic storm. It might at first sight be thought from this last observation that a magnetic storm is due to some direct magnetic influence propagated from the sun to the earth, and accompanying a rapid development of spots, the influence being thus very different from that which may be supposed to cause variations in the magnetic range. But I do not see that this result follows from Prof. Loomis' observations. There is, I think, evidence that the earth before a magnetic storm is in a critical magnetic state—out of relation to its surroundings—and hence a sudden solar outburst may be the immediate occasion of its starting off. But I fail to see any evidence that the influence received from the sun on such occasions is different in kind to that which affects magnetic ranges. For we know that magnetic storms occur most frequently about the equinoxes, or at those times when the sun is crossing the equator. Now were a magnetic storm produced by a magnetic influence immediately proceeding from the sun, it would be difficult to understand why there should be any marked reference in magnetic storms to certain months of the year.

When the magnetism of the earth is in a disturbed state this may of course be rendered visible by means of the oscillations of a delicately suspended magnetic needle. Nevertheless there are associated phenomena of a very conspicuous character which vividly impress us with the reality of the occurrence. One of these is the aurora—displays of which invariably accompany considerable magnetic storms, on which occasions they may be witnessed over a large portion of the globe.

Another of these is the earth currents which on such occasions affect all telegraphic lines connected with the earth. These earth currents are automatically registered at Greenwich by the Astronomer Royal, and their peculiarity is that during magnetic storms they are very violent, passing rapidly and frequently backwards and forwards between positive and negative.

We come now to the meteorological effects produced by the variable state of the sun's surface. More than ten years ago Mr. Baxendell of Manchester pointed out that the convection currents of the earth were apparently altered by the state of the sun's surface, and since that time this peculiar connexion between the sun and the earth has been investigated on an extensive scale by observers in various portions of the globe. Dr. Charles Meldrum of the Mauritius Observatory was one of the first pioneers in this important branch of inquiry. In 1872 he showed that the rainfalls at Mauritius, Adelaide, and Brisbane were greater generally in years of maximum than in years of minimum sun-spots. Shortly afterwards Mr. Lockyer showed that the same law held for the rainfalls at the Cape of Good Hope and Madras. Dr. Meldrum afterwards took twenty-two European observatories, and found that the law held in nineteen out of the twenty-two. It would however appear from the observations of Governor Rawson that at Barbadoes, and perhaps other places, the maximum rainfall does not coincide with the maximum sun-spot years. As locality has a very great influence upon rainfall, it might be supposed that by measuring the recorded depths of water in large rivers and lakes we should be able to integrate the rainfall over a large area, and thus avoid irregularities due to local influence. This too has been attempted. In 1873 Gustav Wex examined the recorded depths of water in the Elbe, Rhine, Oder, Danube, and Vistula for the six sun-spot periods from 1800 to 1867, and came to the conclusion that the years in which the maximum amount of water appeared in these rivers were years of maximum sun-spots, while the minimum amounts of water occurred during the years of minimum sun-spots.

In 1874 Mr. G. M. Dawson, in America, analysing the fluctuations of the great lakes, came to a similar conclusion. This leads me to a very practical and important part of the subject. In countries such as ours we often suffer from excessive rainfall, and are rarely incommoded by excessive heat; but in hot countries such as India a deficient rainfall means a dearth, or even a famine.

This has been brought prominently before us of late years by Dr. Hunter, Director-General of Statistics in India, who has shown that famines are most frequent at Madras about the years of minimum sun-spots—years which were likewise associated with a diminished rainfall.

In summing up the rainfall evidence we ought to bear in mind that the direction as well as the intensity of the earth's convection currents is no doubt altered by solar variability. And if we at the same time reflect how very local rainfall is, we cannot expect that the same rule regarding it should hold for all the various stations of the earth's surface. But on the whole there appears to me to be evidence that we have most rainfall during most sun-spots. Of course we know little or nothing of variations in the rainfall at sea.

I have already mentioned that the magnetic storms of the earth are most frequent during years of maximum sun-spots, and the very same thing may be said of wind-storms. Dr. Meldrum has found that there are more cyclones in the Indian Ocean in years when there are most sun-spots, and fewest cyclones in years when there are fewest sun-spots. M. Poëy has proved a similar coincidence between the hurricanes of the West Indies and the years of maximum sun-spots, and I believe that a similar conclusion has been arrived at with regard to the typhoons of the Chinese seas.

In 1877 Mr. Henry Jeula of Lloyds and Dr. Hunter found that the percentage of casualties on the registered vessels of the United Kingdom was 17½ per cent. greater during the maximum two years than during the minimum two years in the common sun-spot cycle.

We may therefore imagine that the wind as well as the rain of the earth is most violent during years of maximum sun-spots.

We come now to the pressure of the air. If there were no sun the pressure of the air would ultimately distribute itself equally where it is now unequal. This inequality is no doubt caused by the sun, and we should expect it to be most pronounced when the sun has most power. It is also different in summer and winter. In summer we generally find a low barometer in the centres of great continents, and a high barometer over the sea; while during winter we have the converse of this, or a high barometer over continents and a low barometer at sea. I think it likely that the true relation between the variations of sun-spots and of barometric pressure will ultimately be discovered by means of the admirable weather-maps of the United States; meanwhile, however, especially in India, something has already been done in this direction.

If we regard the distribution of isobaric lines, that is to say of lines of equal barometric pressure, we shall find that the Indo-Malayan region is one which for the mean of the year has a barometric pressure probably below the average. Now during years of powerful solar action we might imagine that this peculiarity would be increased. But this is precisely what all the Indian observers have found for years with most sun-spots.

On the other hand Western Siberia in the winter season has a pressure decidedly above the average, and we should therefore imagine that during years of powerful solar action the winter pressure would be particularly high. This again is the state of things that Mr. Blanford has found in his discussion of the Russian stations to correspond with years of most sun-spots.

It therefore appears to me that the barometric evidence as far as it goes is favourable to the belief that years of maximum sun-spots are years of greatest solar power.

I come now to consider the question of temperature. Mr. Baxendell was the first to conclude that the distribution of temperature under different winds, like that of barometric pressure, is very sensibly influenced by the changes which take place in solar activity. In 1870 Prof. Piazzi Smyth published the results of observations made from 1837 to 1869 with thermometers sunk in the rock at the Royal Observatory, Edinburgh. He concluded from these that a heat wave occurs about every eleven years, its maximum slightly lagging behind the minimum of the sun-spot cycle. In 1871 Mr. E. J. Stone examined the temperature observations recorded during thirty years at the Cape of Good Hope, and came to the conclusion that the same cause which leads to an access of mean annual temperature at the Cape leads equally to a dissipation of sun-spots. Dr. W. Köppen in 1873 discussed at great length the connexion between sun-spots and terrestrial temperature, and found that in the tropics the maximum temperature occurs fully a year before the year of minimum sun-spots: while in the zones beyond the tropics it occurs two years after the minimum. The regularity and magnitude of the temperature wave is most strongly marked in the tropics.

The temperature evidence now given appears at first sight to be antagonistic to that derived from the other elements, both of magnetism and meteorology, and to lead us to conclude that the sun heats us most when there are fewest spots on its surface. This conclusion will not, however, be strengthened if we discuss the subject with greater minuteness. Scientifically, we may regard the earth as an engine, of which the sun is the furnace, the equatorial regions the boiler, and the polar regions the condenser. Now this engine works in the following manner. Hot air and vapour are carried along the upper regions of the atmosphere from the equator to the poles by means of the anti-trade winds, while in return the cold polar air is carried along the surface of the earth from the poles to the equator, forming what is known as the trade winds. Now whenever the sun's heat is most powerful, both trades and anti-trades should, I imagine, be most powerful likewise. But we live in the trades rather than in the anti-trades—in the surface currents, and not in the upper currents of the earth's atmosphere. When the sun is most powerful, therefore, is it not possible that we might have a particularly strong and cold polar current blowing about us? The same thing would happen in the case of a furnace-fire—the stronger the fire the more powerful the hot draught up the chimney—the more powerful also the cold draught from without along the floor of the room. It might thus follow that a man standing in the furnace room near the door might be chilled rather than heated when the furnace itself was roaring loudest. In fact temperature is a phenomenon due to many causes. Thus a low temperature may be due

(1) To a deficiency in solar power.
(2) To a clouded sky.
(3) To cold rain.
(4) To cold winds.
(5) To cold water and ice.
(6) To cold produced by evaporation.
(7) To cold produced by radiation.

Now Mr. Blanford, the Indian observer, has recently shown that a low temperature of the air and soil is accompanied in the stations which he has examined by a copious rainfall and by a large number of clouds. If therefore we regard a high rainfall as the concomitant of many sun-spots, we must not be surprised if this is sometimes accompanied with a low temperature, nor hastily conclude from this lowering of temperature that the sun is less rather than more powerful. Considerations of this nature have induced me to think that the true connexion between sun-spots and terrestrial temperature is more likely to be discovered by a study of short-period inequalities of sun-spots than by that of the eleven-year period in which there is time enough to change the whole convection system of the earth. I have accordingly discussed at some length two prominent sun-spot inequalities of short periods (about twenty-four days), and endeavoured to see in what way they affect the terrestrial temperature. From this it appears that a rapid increase of sun-spots is followed in a day or two by an increase of the diurnal temperature range at Toronto. Now an increase of diurnal temperature range surely denotes an increase of solar energy, and we are thus led to associate an increase of solar heat with a large development of spots.

I have thus brought before you a quantity of evidence, chiefly indirect, tending to prove that the sun's rays are most powerful when there are most spots. But you will naturally ask why I have not given you any direct evidence on this point. Is it not possible, you ask, to measure the direct heating effect of the sun's rays, so as to decide the question without further circumlocution? Now, strange to say, this has not been done.

We call an instrument that measures the sun's direct influence an actinometer, and I will now briefly allude to two such instruments, one for measuring the chemical effect of the sun's rays devised by Dr. Roscoe, and another for measuring the heating effect of the sun's rays, devised by myself. (The lecturer here described the mode of action of these actinometers.)

But the use of such instruments is rather a problem of the future than of the past. Hitherto it cannot be said that we have determined by actual observation whether the sun's rays are more powerful or less powerful at times of maximum sun-spots. I may, however, quote the actinometrical observations made in India at Mussooree and Dehra by Mr. J. B. N. Hennessey as confirming, so far as the evidence goes, the hypothesis of greater solar energy at maximum than at minimum epochs.

My trust is that for the future India will throw great light upon the problem we are now discussing. We have a distinguished meteorologist, General Strachey, as member of the Council of India, we have General Walker and the trigonometrical survey staff, and we have Mr. Blandford and the various meteorological and magnetic observers of India, and I am glad to think that neither solar nor actinometric observations are likely to be forgotten.

Let me now briefly recapitulate the conclusions we have come to.

In my first lecture I endeavoured to bring before you theoretical grounds for imagining that the sun is most powerful when there are most spots on its surface.

This has been supported by the evidence of a meteorological nature derived from these observations of rainfall, wind, barometric pressure, and temperature which have now been discussed, and likewise from such actinometric observations as have been made in Mussorree and Dehra. With regard to magnetical observations, we have the fact that diurnal declination ranges are largest in times of maximum sun-spots, and that on such occasions we have likewise a great number of magnetic storms, accompanied with earth currents and displays of the aurora. In fine we have most magnetic activity when there are most spots. There may perhaps be some doubt as to the exact method by which solar phenomena affect the magnetism of the earth, but we have already hypotheses from two distinguished physicists, the late Prof. Faraday and Prof. Stokes, while others have likewise been engaged in similar speculations.

Thus we may hope that eventually the truth will be attained. Meanwhile however we may conclude that the earth is most active both meteorologically and magnetically when there are most spots on the sun's surface. And if this be so, who will say that this is not a problem of great practical as well as of great theoretical importance?

ON GAS SUPPLY BOTH FOR HEATING AND ILLUMINATING PURPOSES[1]

WHEN, within the memory of living men, the gas-burner took the place of the time-honoured oil-lamp, the improvement, both as regards the brilliancy of the light and the convenience of the user, was so great that the ultimate condition of perfection appeared to have been reached. Nothing apparently remained for the engineer to effect but improvements in the details of the works and apparatus, so that this great boon of modern times might be utilised to the largest extent. It is only in recent years that much attention has been bestowed upon the utilisation of by-products, with a view of cheapening the cost of production of the gas, and that the consumer has become alive to the importance of having a gas of high illuminating power and free from nauseous constituents, such as bisulphide of carbon, thus providing a gentle stimulant for steady progress on the part of the gas-works manager.

This condition of steadiness and comfort has been somewhat rudely shaken by the introduction within the last year or two of the electric light, which, owing to its greater brilliancy and cheapness, threatens to do for gas what gas did for oil half a century before. The lighting of the City of London and of many public halls and works furnishes indisputable proof that the electric light is not an imaginary, but a real and formidable competitor to gas as an illuminant, and it is indeed time for gas engineers and managers to look seriously to their position with regard to this new rival; to decide whether to meet it as a foe, and contest its progress inch by inch, or to accept at once the new condition of things, conceding the ground that cannot reasonably be maintained, and to look about in search of such compensating fields as may be discovered for a continuation or extension of their labours.

For my own part I present myself before you both as a rival and as a friend; as a rival, because I am one of the promoters of electric illumination, and as a friend, because I have advocated and extended the use of gas for heating purposes during the last twenty years, and am by no means disposed to relinquish my advocacy of gas both as an illuminating and as a heating agent. Speaking as a gas engineer, I should be rather disposed to regard the electric light as a welcome incentive to fresh exertion, confidently anticipating achievements by the use of gas which would probably have been long postponed under the continued *régime* of a monopoly. Already we observe, both in our thoroughfares and in our apartments, gas-burners producing a brighter and more powerful light than was to be seen previously; and although gas will have to yield to the electric light the illumination of our lighthouses, halls, and great thoroughfares, it will be in a position, I believe, to hold its own as a domestic illuminant, owing to its great convenience of usage, and to the facility with which it can be subdivided and regulated. The loss which it is likely to sustain in large appliances as an illuminant would be more than compensated by its use as a heating agent, to which the attention of both the producer and the consumer has latterly been largely directed.

Having in the development of the regenerative gas-furnace had exceptional opportunities of recognising the many advantages of gaseous over solid fuel, I ventured, as early as 1863, to propose to the Town Council of Birmingham the establishment of works for the distribution of heating gas throughout the town, and it has occurred to me to take this opportunity (when the gas managers of Great Britain hold their annual meeting at the very place of my early proposal) to place before them the idea that then guided me, and to suggest a plan of operation for its realisation which at the present day will not, I venture to hope, be regarded by them as Utopian. The proposal of 1863 consisted in the establishment of separate mains for the distribution of heating gas, to be produced in vertical retorts, that might be shortly described as Appold's coke oven heated by means of "producer" gas and "regenerators." The heat of the retorts was to be increased beyond the ordinary limit in order to produce a coke suitable for locomotive and other purposes; and the gas produced being possessed of less illuminating but of the same heating power, and being, with a view to cheapness, less thoroughly purified than ordinary retort gas, was to be distributed through the town as a heating agent, to be applied to the small boilers and furnaces of the numerous little factories peculiar to the district, as well as for domestic purposes. The Corporation applied for an Act of Parliament, but did not succeed in obtaining it, owing to the opposition of the existing gas companies, who pledged themselves to carry out such an undertaking if found feasible by them. I am ready to admit that at the time in question the success of the undertaking would have involved considerable practical difficulty, but I feel confident that the modified plan which it is my present object to bring before you would reduce those difficulties to a minimum, and open out on the other hand a new field of vast proportions for the enterprise and energy of those interested in gas-works, and of great benefit to the public.

The gas-retort would be the same as at present, and the only change I would advocate in the benches is the use of the regenerative gas-furnace. This was first successfully introduced by me at the Paris Gas-works in 1863, and has since found favour with the managers of gas-works abroad and in this country. The advantages that have been proved in favour of this mode of heating are economy of fuel, greater durability of retorts, owing to the more perfect distribution of heat, the introduction of an additional retort in each bed in the position previously occupied by the fire-grate, and above all, a more rapid distillation of the coal, resulting in charges of four hours each, whereas six hours are necessary under the ordinary mode of firing. The additional suggestion I have now to make consists in providing over each bench of retorts two collecting pipes, the one being set aside for illuminating, and the other for a separate service of heating gas. I shall be able to prove to you from unimpeachable evidence that the gas coming from a retort varies very greatly in its character during progressive periods of the charge; that during the first quarter of an hour after closing the retort, the gas given off consists principally of marsh gas (CH_4) and other occluded gases and vapours, which are of little or no use for illuminating purposes; from the end of the first quarter of an hour, for a period of two hours, rich hydrocarbons, such as acetylene (C_2H_2) and olefiant gas (C_2H_4) are given off; whereas the gases passing away after this consist for the most part again of marsh gas possessing low illuminating power.

M. Ellissen, the late chief of the experimental department of the Paris Gas-works, and actual President of the French Society of Gas Engineers, has favoured me with the result of a most interesting series of experiments, which he carried out in connection with the late M. Regnault, the eminent physicist, some years ago, the object of the experiments being to discover the proper period of time to be allowed for each charge.

The results of these experiments are given in a diagram showing in a striking manner that although the average illu-

[1] Paper read before the British Association of Gas Managers at Birmingham, June 14, by C. W. Siemens, D.C.L., F.R.S., Civil Engineer.

minative power produced by the distillation of the coal did not exceed 1·35 Carcel burners, or 13·5 standard candles, according to our English mode of measurement, the gas given off from the end of the first quarter of an hour, during a period of two hours, possessed an illuminating power of 1·616 Carcel burners, or 16·16 standard candles. According to the figures given in the valuable experiments of M. Ellissen, it appears that nearly two-thirds of the total production of gas takes place in the above period, whilst the remaining third is distilled during the first quarter of an hour and the last hour and three quarters. It hence follows that by changing the direction of the flow of gas at the periods indicated, allowing the first results of distillation to flow into the heating gas-main, then for two consecutive hours into the illuminating gas main, and for the remainder of the period again into the heating gas-main, one-third volume of heating and two-thirds of illuminating gas would be obtained, with this important difference, that the illuminating gas would be of 16·16 instead of 13·5 candle-power, and that the heating gas, although possessed of an illuminating power of only 11·05, would be preferable to the mixed gas for heating purposes, in being less liable to deposit soot in its combustion upon heat-absorbing surfaces, and in giving, weight for weight, a calorific power superior to olefiant gas.

These experiments not having been made for the particular objects I have in view, no account was taken of the quantity or quality of the gas coming from the retort during the first quarter of an hour. Judging by the nature of the curves given by M. Ellissen, it is reasonable to suppose that during the first quarter of an hour a considerable quantity of gas of very inferior illuminating power is given off, which, if taken into account, would still further improve the result given in favour of separating the illuminating from the heating gases.

It will be observed that although the candle-power of the illuminating gas would be raised to only 16·25 if two-thirds of the gas were set apart for this purpose, *i.e.* after the first 25 minutes of distillation up to 2h. 35m. from the commencement of the charge, a gas equal to 18·04 candles would be obtained if the proportionate quantity of heating and illuminating gas were reversed, which might be effected by continuing the distillation for illuminating purposes from 0·25m. to 1h. 27m. after the commencement of the charge, whilst if equal quantities of heating and illuminating gas were produced, which would result from allowing the illuminating gas to flow into its receiver from 0·25m. to 2h. 0m., the candle-power of this portion of the gas would be raised to 16·78 candles, as shown in the figures given below.

	Cubic Feet.	Candle-power.	
Total gas produced from ton of coal...	10573·20 of	13·50	
	Illuminating Gas.		Heating Gas
	Cubic Feet.	Candle-power.	Cubic Feet.
Illuminating gas passing into its main 25 minutes after commencement of charge:—			
If two-thirds the quantity used for illumination from 0h. 25m. to 2h. 35m.	7048·8	16·25	3524·4
If half the quantity used for illumination from 0h. 25m. to 2h. 0m.... ...	5286·6	16·78	5286·6
If one-third the quantity used for illumination from 0h. 25m. to 1h. 27m...	3524·4	18·04	7048·8

These important results are borne out by a series of photographic observations which were made some years ago by Mr. Sugg, which Mr. Sugg has further supplemented verbally in stating that the average illuminative power obtained by the distillation of Newcastle coal might be taken at 14 candle-power, whilst two-thirds of the quantity, if separated in the manner I propose, would produce an average of 16 candles.

The working out of this plan would involve the mechanical operation of changing the direction of the gas coming from each bench of retorts at the proper periods of the charge; this could be accomplished by means of a simple reversing valve similar to that applied for many years in reversing the current of the regenerative gas-furnace, and a sand-glass may be placed in front of each bench of retorts for the guidance of the man in charge as to the time when the reversal should be made. In order to distribute the two gases a double set of gas-mains would certainly be required; but these exist already in the principal thoroughfares of many of our great towns, where at one period or another competing gas companies have been established, and it would not be difficult, I think, to utilise these services for the separate supply of illuminating and heating gas, the latter being taken into such houses and establishments only where asked for by the occupiers.

The public could well afford to pay an increased price for a gas of greatly increased illuminating power, and the increase of revenue thus produced would enable the gas companies to supply heating gas at a proportionately reduced rate. It would not be necessary to employ upon the heating gas the same expense and trouble in purification as is required for illuminating gas, because the products of combustion of the heating gas would not as a rule enter the apartments, but be conducted into the atmosphere through the ordinary chimneys. Heating the retorts by means of the regenerative gas-furnace would, as already indicated, lead to an increased production of gas from each bench of retorts, and thus compensate for the reduced amount of illuminating gas in each operation. The heating gas might without inconvenience be sent through the pipes at a greater pressure than the illuminating gas, in order to make a given plant of mains transmit an increased quantity.

The question may fairly be asked whether a demand would be likely to arise for heating gas similar in amount to that for illuminating gas, and I may state that I am decidedly of opinion that although at the present moment the amount of gas supplied for illuminating purposes exceeds that for heating, the diminution in price of the latter would very soon indeed reverse these proportions. Already gas is used in rapidly increasing quantities for kitcheners, for the working of gas-engines, and for fire-grates. As regards the latter application, I may here mention that an arrangement for using gas and coke jointly in an open fire-place, combined with a simple contrivance (with a view of effecting the combustion of the gas by heated air), has found favour with many of the leading grate builders and with the public; although this arrangement was suggested by me only last winter, several hundred of these grates are already in use in London, Manchester, Leeds, Glasgow, and other towns, showing how fully alive the public are at the present time to that great crying evil, "the smoke nuisance."

It may be as well for me to mention here, that neither the regenerative gas-coke fire-grate just alluded to, nor the plan I here advocate of separating the produce of gas-retorts, has been made by me subject-matter of letters patent, my time being already too much occupied in other directions to give that amount of constant attention to these subjects which the working of a patent necessitates.

As regards the use of illuminating gas, I have one more suggestion to make, which I feel confident will be viewed by you not without interest. The illuminating effect produced in a gas flame depends partly upon the amount of carbon developed in the solid condition in the body of the flame, and partly upon the temperature to which these particles are heated in the act of combustion. Having already shown how by separation a gas of greater luminosity may be supplied, it remains to be seen how the temperature of combustion may be raised. This may be effected to an extent that seems surprising by certain mechanical arrangements, whereby a portion of the waste heat produced by the flame itself is rendered available to heat the gas and air sustaining the combustion of the flame, say to 600° F., or even beyond that point.

The arrangement I have adopted for this purpose is represented on the sectional diagram, and I have also the pleasure to place the burner itself before you to enable you to test its efficiency by actual trial. The burner is of the ordinary Argand type, mounted in a small cylindrical chamber of sheet copper connected with a vertical rod of copper projecting up and through the centre of the burner, and terminating in a cup-like extension at a point about four inches above the gas orifices, or on a level with the top of the flame. A small mass of fire-clay fills the cup, projecting upwards from it in a rounded and pointed form. The copper vessel surrounding the burner is contracted at its upper extremity with a view of directing a current of air against the gas jets on the burner, and on its circumference it is perforated for the admission of atmospheric air. The bottom surface is formed of a perforated disk covered with wire gauze, and wire gauze also surrounds the circumference of the perforated cylinder. The external air is heated in passing through these "regenerative" surfaces, and the flame is thus fed with air, heated to the point above indicated, which by more elaborate arrangements might be raised to a still higher degree. The ball of fire-clay in the centre of the burner, which is heated to red-

ness, serves the useful purpose of completing the combustion of the gas, and thus diminishes the liability to blackening of the ceiling.

This arrangement for transferring the heat from the tip of the flame to the air supporting its combustion is applicable also to an open batswing burner; but I have not yet had time to ascertain accurately the amount of increase of luminosity that may be realised with this class of burner.

I may here mention that another solution of the problem of heating the incoming air by the waste heat of the products of combustion has lately been brought under public notice by my brother, Frederick Siemens, which differs essentially from the plan I have suggested, inasmuch as he draws the flame downwards through heating apparatus, and thence into a chimney. Experiments made officially and with great care have proved that by these methods the luminous effect of gas can be practically doubled. In practice both these methods of intensifying a gas-flame will probably find independent application according to circumstances, the cause of increased luminous effect being in both cases the same.

From a purely theoretical point of view it can be shown that of the caloric energy developed in the combustion of gas, a proportion probably not exceeding 1 per cent. is really utilised in the production of luminous rays, and that even in the electric light nine-tenths of the energy set up in the arc is dispersed in the form of heat, and one-tenth only is utilised in the form of luminous rays. It would lead us too far here to go into the particulars of these calculations, but it is important to call attention to them, in order to show the large margin for practical improvements still before us.

By the combined employment of the process of separation of the illuminating from the heating gas with the arrangement for intensifying the luminosity of the gas-flame, the total luminous effect produced by a given consumption of coal gas may be nearly tripled, thus showing that the deleterious effects now appertaining to gas illumination are not inseparably connected with its use.

My principal object in preparing this communication has been to call your attention generally to the important question of an improved gas illumination, and more particularly to the subject of a separate supply for heating gas, which, if carried into effect, would lead, I am convinced, to beneficial results, the importance of which, both to gas companies and to the public, it would be difficult to over-estimate.

APPENDIX

Paris, June 4, 1881

DEAR SIR,—I send you herewith the result of my experiments, together with tables and curves; the very ingenious proposal that you have made would permit such a division of the total production of gas, that two-thirds could be employed for lighting and one-third for heating purposes, resulting in splendid illumination and much more rational heating.

I am, dear sir, &c.,

Dr. C. William Siemens A. ELLISSEN

Experiments on the Variation of Production of Gas, and of its Illuminating Power at different Periods of the Distillation

Tables I. and II. contain the results of experiments made in a bench of seven retorts of the type of the Compagnie Parisienne, each retort being charged respectively with 100, 110, and 120 kilogrammes (220, 242, 264 pounds).

Table I. corresponds to a distillation of 4 hours.

Table II. corresponds to a distillation of 4h. 48m.

The period of distillation has been divided into intervals of fifteen minutes, and the results recorded on each horizontal line refer to the gas produced during the quarter ending the time mentioned on each line.

In each of the two tables the case of a charge of 110 kilos. (242 lbs.) has been chosen as the standard, and the results have been graphically represented by means of two curves, one in red for the gas produced, and the other in blue for the illuminating power.

The line of abscissæ being divided into equal parts, each representing fifteen minutes, each ordinate of the red curve gives the gas produced during the preceding quarter of an hour, and the corresponding ordinate of the blue curve indicates the illuminating power of this same gas.

The production of the gas been further divided into two portions, the one destined for illumination, and the other for heating and motive power.

The gas produced during the first quarter of an hour is generally of low illuminating power, and varies besides with the hygrometric condition of the coal; it has, in the following calculation, been accordingly classed with the heating gas, and the gas produced during the interval from 0h. 15m. to 2h. 15m. of the working has alone been reserved for illuminating purposes.

Distillation in four hours. Charge of 110 *kilos.* (242 *lbs.*)

I. Gas produced per 100 kilos. of coal distilled—

	Cubic metres.	Per ton, cubic feet.
1. From 0h. 15m. to 2h. 15m. ...	18·062	6502·32
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 0m. ...	11·308	4070·88
Total	29·370	10573·20

II. Gas produced per 100 cubic metres obtained—

	Cubic metres.
1. From 0h. 15m. to 2h. 15m. ...	61·502
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 0m. ...	38·498
Total	100·000

III. Mean illuminating power of the produced gas—

	Litres.	In English standard candles.
1. From 0h. 15m. to 2h. 15m. ...	87·7	16·16
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 0m. ...	128·2	11·05
Mean of the total mixed gas as per calculation	103·3	
Illuminating power of mixed gas as per direct trial...	105·7	13·50

Distillation in 4 *hours* 48 *minutes. Charge of* 110 *kilos.* (242 *lbs.*)

I. Gas produced per 100 kilos. of coal distilled—

	Cubic metres.	Per ton, cubic feet.
1. From 0h. 15m. to 2h. 15m. ...	20·388	7339·68
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 48m. ...	9·741	3506·76
Total	30·129	10846·44

II. Gas produced per 100 cubic metres obtained—

	Cubic metres.
1. From 0h. 15m. to 2h. 15m. ...	67·673
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 48m. ...	32·327
Total	100·000

III. Mean illuminating power of the produced gas—

	Litres.	In English standard candles.
1. From 0h. 15m. to 2h. 15m. ...	101·1	14·02
2. From 0h. 0m. to 0h. 15m., and from 2h. 15m. to 4h. 48m. ...	132·4	10·07
Mean of the total mixed gas	111·2	12·77

It is not proposed to stop at the results obtained by distillation in 4h. 48m., that is five charges per twenty-four hours; experience has proved that the best conditions of working are found in the use of active charges rapidly distilled by raising the temperature of the furnaces.

From these experiments it results that it would be possible to divide the products of distillation of coal into illuminating gas, and gas for heating purposes and motive power.

Thus in place of producing, as is generally done, by means of a distillation of four hours and 110 kilos. (242 lbs.) per retort, a mean result per 100 kilos of coal distilled, of 30 cubic metres of normal gas, which corresponds to an expenditure of 105 litres, to produce the light of a Carcel burner consuming 42 grammes of oil per hour, there may be produced:—

1. About 18·5 cubic metres of illuminating gas of an illuminative power of 87 litres; and

2. About 11·5 cubic metres of heating and motive-power gas of an illuminative power of 128 litres; or per 100 cubic metres

of gas produced, 61·50 cubic metres of illuminating gas, and 38·50 cubic metres of heating and motive-power gas.

This result would be obtained by receiving into separate reservoirs the gas produced during the first fifteen minutes, and during the last 1h. 45m. of the distillation, and in reserving for illuminating purposes the gas made in the interval of 0h. 15m. to 2h. 15m. of the charge from the commencement of the distillation.

STORAGE OF ELECTRIC ENERGY

THE following correspondence on this subject has appeared in the *Times*. By help of this and the communication in our issue of to-day from Sir W. Thomson, the reader will be able to understand the present position of this important question.

THE marvellous "box of electricity" described in a letter to you, which was published in the *Times* of May 16, has been subjected to a variety of trials and measurements in my laboratory for now three weeks, and I think it may interest your readers to learn that the results show your correspondent to have been by no means too enthusiastic as to its great practical value. I am continuing my experiments to learn the behaviour of the Faure battery in varied circumstances, and to do what I can towards finding the best way of arranging it for the different kinds of service to which it is to be applied. At the request of the Conseil d'Administration of the Société de la Force et la Lumière, I have gladly undertaken this work, because the subject is one in which I feel intensely interested, seeing in it a realisation of the most ardently and unceasingly felt scientific aspiration of my life—an aspiration which I scarcely dared to expect or to hope to live to see realised.

The problem of converting energy into a preservable and storable form, and of laying it up in store conveniently for allowing it to be used at any time when wanted, is one of the most interesting and important in the whole range of science. It is solved on a small scale in winding up a watch, in drawing a bow, in compressing air into the receiver of an air-gun or of a Whitehead torpedo, in winding up the weights of a clock or other machine driven by weights, and in pumping up water to a height by a windmill (or otherwise, as in Sir William Armstrong's hydraulic accumulator) for the purpose of using it afterwards to do work by a waterwheel or water pressure on a piston. It is solved on a large scale by the application of burning fuel to smelt zinc, to be afterwards used to give electric light or to drive an electro-magnetic engine by becoming, as it were unsmelted in a voltaic battery. Ever since Joule, forty years ago, founded the thermodynamic theory of the voltaic battery and the electro-magnetic engine, the idea of applying the engine to work the battery backwards and thus restore the chemical energy to the materials so that they may again act voltaically, and again and again, has been familiar in science. But with all ordinary forms of voltaic battery the realisation of the idea to any purpose seemed hopelessly distant. By Planté's admirable discovery of the lead and peroxide of lead voltaic battery, alluded to by your correspondent, an important advance towards the desired object was made twenty years ago; and now by M. Faure's improvement practical fruition is attained.

The "million of foot pounds" kept in the box during its seventy-two hours' journey from Paris to Glasgow was no exaggeration. One of the four cells, after being discharged, was recharged again by my own laboratory battery, and then left to itself absolutely undisturbed for ten days. After that it yielded to me 260,000 foot pounds (or a little more than a quarter of a million). This not only confirms M. Reynier's measurements, on the faith of which your correspondent's statement was made; it seems further to show that the waste of the stored energy by time is not great, and that for days or weeks, at all events, it may not be of practical moment. This, however, is a question which can only be answered by careful observations and measurements carried on for a much longer time than I have hitherto had for investigating the Faure battery. I have already ascertained enough regarding its qualities to make it quite certain that it solves the problem of storing electric energy in a manner and on a scale useful for many important practical applications. It has already had in this country one interesting application, of the smallest in respect to dynamical energy used, but not of the smallest in respect to beneficence, of all that may be expected of it. A few days ago my colleague, Prof. George Buchanan, carried away from my laboratory one of the lead cells (weighing about 18 lbs.) in his carriage, and by it ignited the thick platinum wire of a galvanic *écraseur* and bloodlessly removed a nævoid tumour from the tongue of a young boy in about a minute of time. The operation would have occupied over ten minutes if performed by the ordinary chain *écraseur*, as it must have been had the Faure cell not been available, because in the circumstances the surgical electrician, with his pharaphernalia of voltaic battery to be set up beforehand, would not have been practically admissible.

The largest useful application waiting just now for the Faure battery—and it is to be hoped that the very *minimum* of time will be allowed to pass till the battery is supplied for this application—is to do for the electric light what a water cistern in a house does for an inconstant water supply. A little battery of seven of the boxes described by your correspondent suffices to give the incandescence in Swan or Edison lights to the extent of 100 candles for six hours, without any perceptible diminution of brilliancy. Thus, instead of needing a gas engine or steam engine to be kept at work as long as the light is wanted, with the liability of the light failing at any moment through the slipping of a belt—an accident of too frequent occurrence—or any other breakdown or stoppage of the machinery, and instead of the wasteful inactivity during the hours of day or night when the light is not required, the engine may be kept going all day and stopped at night, or it may be kept going day and night, which will undoubtedly be the most economical plan when the electric light comes into general enough use. The Faure accumulator, always kept charged from the engine by the house supply wire, with a proper automatic stop to check the supply when the accumulator is full, will be always ready at any hour of the day or night to give whatever light is required. Precisely the same advantages in respect of force will be gained by the accumulator when the electric town supply is, as it surely will be before many years pass, regularly used for turning lathes and other machinery in workshops and sewing-machines in private houses.

Another very important application of the accumulator is for the electric lighting of steam-ships. A dynamo-electric machine of very moderate magnitude and expense, driven by a belt from a drum on the main shaft, working through the twenty-four hours, will keep a Faure accumulator full, and thus, notwithstanding irregularities of the speed of the engine at sea or occasional stoppages, the supply of electricity will always be ready to feed Swan or Edison lamps in the engine-room and cabins, or arc lights for mast-head and red and green side lamps, with more certainty and regularity than have yet been achieved in the gas supply for any house on *terra firma*.

I must apologise for trespassing so largely on your space. My apology is that the subject is exciting great interest among the public, and that even so slight an instalment of information and suggestions as I venture to offer in this letter may be acceptable to some of your readers. WILLIAM THOMSON.

The University, Glasgow, June 6.

ALTHOUGH agreeing with every word of Sir William Thomson's letter in the *Times* of to-day, and entirely sympathising with his enthusiasm as regards the marvellous box of electricity, still I feel that it would have been desirable if in pointing out the importance of this new discovery Sir William Thomson had guarded against a very probable misconstruction of the purport of his letter.

The means of storing and re-storing mechanical energy form the aspiration not only of Sir William, but of every educated mechanic. It is, however, a question of degree—of the amount of energy stored as compared with the weight of the reservoir, the standard of comparison being coal and corn. Looked at in this way one cannot but ask whether, if this form of storage is to be the realisation of our aspirations, it is not completely disappointing. Large numbers are apt to create a wrong impression until we inquire what is the unit. Eleven million foot pounds of energy is what is stored in 1 lb. of ordinary coal. So that in this box, weighing 75 lb., there was just as much energy as in 1½ oz. of coal, which might have been brought from Paris or anywhere else in a waistcoat pocket, or have been sent by letter.

When we come to the question of the actual conveyance of energy for mechanical purposes, this view is of fundamental importance. The weight of the same amount of energy in the new form is 800 times greater than the equivalent amount of coal; and as a matter of economy, supposing that energy in this

form might be had at a certain spot and no capital were required for its conversion or storage, and that the energy were directly applicable it could not be carried ten miles—that is to say, such energy cannot be economically useful ten miles from its source, although coal had to be carried 100 miles to the spot. This limit, in truth, falls far short of what has been already attained by other means. By wire ropes and by compressed air or steam energy may be economically transmitted from ten to twenty miles. So that if this is the utmost of what is to be done by means of the storage of electricity this discovery adds another door to those which are hopelessly closed against the possibility of finding in Niagara or other water power a substitute for our coal, even when the object is motive power, and much more for that purpose for which five-sixths of our coal is used—the production of heat.

It is very important that the people of this country should not shut their eyes to the fact that, so far from there being a greater prospect of the solution of the problem than when, about twenty years ago, Prof. Jevons raised the alarm, the prospect is now much smaller. In the meantime the capabilities of steel ropes, fluids in pipes, and electricity along conductors have been not only investigated, but practically tested, and found altogether wanting. And now it would seem that the storage of electricity must be added to the list. OSBORNE REYNOLDS

Owens College, June 9

YOUR leading article in the *Times* of yesterday, on the storage of electricity, alludes to my having spoken of Niagara as the natural and proper chief motor for the whole of the North American Continent. I value the allusion too much to let it pass without pointing out that the credit of originating the idea and teaching how it is to be practically realised by the electric transmission of energy is due to Mr. C. W. Siemens, who spoke first, I believe, on the subject in his presidential address to the Iron and Steel Institute in March, 1877. I myself spoke on the subject in support of Mr. Siemens's views at the Institution of Civil Engineers a year later. In May, 1879, in answer to questions put to me by the Select Committee of the House of Commons on Electric Lighting, I gave an estimate of the quantity of copper conductor that would be suitable for the economical transmission of power by electricity to any stated distance; and, taking Niagara as example, I pointed out that, under practically realisable conditions of intensity, a copper wire of half an inch diameter would suffice to take 26,250 horse-power from water-wheels driven by the Fall, and (losing only 20 per cent. on the way) to yield 21,000 horse-power at a distance of 300 British statute miles; the prime cost of the copper amounting to 60,000*l.*, or less than 3*l.* per horse-power actually yielded at the distant station. WILLIAM THOMSON

The University, Glasgow, June 9

IF you do me the honour to publish a letter which I wrote to you yesterday regarding the electric transmission of energy it will be seen that I thoroughly sympathise with Prof. Osborne Reynolds in his aspirations for the utilisation of Niagara as a motor, but that neither Mr. Siemens nor I agree with him in the conclusion which he asserts in his letter to you, published in the *Times* of to-day, that electricity has been tried and found wanting as a means for attaining such objects. The *transmission* of power was not the subject of my letter to you published in the *Times* of the 9th inst., and Prof. Reynolds' disappointment with M. Faure's practical realisation of electric *storage*, because it does not provide a method of *porterage* superior to conduction through a wire, is like being disappointed with an invention of improvements in water cans and water reservoirs because the best that can be done in the way of movable water cans and fixed water reservoirs will never let the water-carrier supersede water-pipes wherever water-pipes can be laid.

The 1½ oz. of coal cited by Prof. Osborne Reynolds as containing a million of foot-pounds stored in it is no analogy to the Faure accumulator containing the same amount of energy. The accumulator can be re-charged with energy when it is exhausted, and the fresh store drawn upon when needed, without losing more than 10 or 15 per cent. with arrangements suited for practical purposes. If coal could be unburned—that is to say, if carbon could be extracted from carbonic acid by any economic process of chemical or electric action, as it is in nature by the growth of plants drawing on sunlight for the requisite energy—the result would be analogous to what is done in Faure's accumulator. WILLIAM THOMSON

The University, Glasgow, June 11

DR. MIKLUCHO MACLAY'S ANTHROPOLOGICAL AND ANATOMICAL RESEARCHES IN MELANESIA AND AUSTRALIA[1]

AFTER I had left Sydney in March, 1879, I visited the following islands: New Caledonia, Lifu; of the New Hebrides: Tana, Vate, Tongoa, Mai, Epi, Ambrim, Malo, Vanua Lava; the Admiralty Islands; the groups—Lub (or Hermit), Ninigo (Echiquier), Trobriant, the Solomon Islands, the islands at the south-east end of New Guinea, and the islands of Torres Straits.[2]

Only a very few of the results of the journey can be comprehended in a short *résumé*, of these the first two of the following appear to me to be the most important:—1. Many islands of Melanesia[3] (especially some of the islands of the New Hebrides, of the Solomon Group, of the Louisiades, New Ireland, &c., &c.) possess a well-marked brachycephalic population (the breadth-index of many heads exceeds eighty, and sometimes even eighty-five), which circumstance is assuredly not ascribable to a mixture with another race, and proves that brachycephalism has a much wider range in Melanesia than has been hitherto supposed. This is a result of numerous careful measurements of heads and skulls[4] of the aboriginals of different islands of Melanesia. 2. Although in some villages of the southern coast of New Guinea there is noticeable a Polynesian admixture, yet this circumstance by no means permits of the aboriginals of the south-eastern peninsula (who are a branch of the Melanesian stock) being called a "yellow Malayan race," as has been frequently done of late years. 3. An acquaintance with the languages of the group Lub (or Hermit) and the dialects of the northern coast of the large island of the Admiralty Group, as well as the native traditions of the former, has shown that the population of the group Lub emigrated from the Admiralty Islands. Further acquaintance with the natives of Lub proved that there is among them a Polynesian admixture, which has resulted from the carrying off of the women of the group Ninigo, and from a frequent intercourse with the inhabitants (also a Melano-Polynesian race) of the smaller group Kaniet or Kanies (or Anchorites). My stay among the inhabitants of the Admiralty Islands has afforded me a glimpse of many interesting customs of the islands; but an account of these observations and researches cannot be condensed within the compass of a few sentences. To this series of results belong also the observations which I never neglected to make during the journey in Melanesia whenever the opportunity presented itself—especially observations on their customs, such as the deformation of the head, tattooing, perforation of the septum narium, alæ nasi, lobes and margins of the ears. I have also succeeded in making further observations, and obtaining more information, on the macrodontism in the Admiralty and Lub islands.

On my way back from the islands of Torres Straits I visited Brisbane, where I at first only intended to remain a few days. Here however a favourable opportunity presented itself of acquiring some interesting anatomical material for my anthropological researches, which circumstance induced me to prolong my stay for several months. I found, namely, that there was a possibility of continuing my researches on the comparative anatomy of the brain of the different varieties of the genus *homo*, which were commenced in 1873 in Batavia and resumed in Sydney in 1878. Although the material in question consisted only of three brains, yet I find that this new contribution to our knowledge of race-anatomy supports the view which I may briefly summarise as follows:—The investigation of the brains of representatives of different races of men shows that there occur peculiarities of by no means trifling import, which one cannot regard as individual variations. To this category belong differences in the development of the corpus callosum of the pons varolii, of the cerebellum; differences in the volume of the cranial nerves, and so forth; also the arrangement of the convolutions of the cerebrum is different, and I believe that in

[1] From a paper read before the Linnean Society of New South Wales February 23, 1881, by Dr. N. De Miklucho-Maclay. Revised and transmitted by the author.

[2] A more detailed account of the route, of the time spent at the different places, with sketch-maps of the routes and other details, will be found in my communication to the Imperial Russian Geographical Society, in the Jswestija of the Society.

[3] By the name "Melanesians" I designate exclusively the frizzly-haired inhabitants of the South Sea Islands.

[4] In order to eliminate any doubt as to the correctness of the cranial measurements on living individuals, I have not neglected to collect a considerable number of undoubtedly authentic skulls from New Caledonia, New Guinea, the Admiraltys, Ninigo, and Solomon Islands.

course of time it will probably be discovered that there exist certain definite types of cerebral convolutions corresponding to the principal varieties of mankind. In order to discover those types much material will require to be conscientiously examined; and I hope that my investigation will induce other anatomists to work in this direction to prove or to disprove this statement, which in the present state of our knowledge can only be more or less hypothetical.

On my way from Thursday Island I let slip no opportunity of examining, measuring, and photographing the remnant of the Australian aboriginals; and hearing it stated in various quarters that there were living in the interior of Queensland certain natives described as devoid of hair, I thought the problem of a possible occurrence of a hairless stock among the aboriginals worthy of a personal investigation. I have written to Prof. Virchow of Berlin at length concerning my examination of this hairless family, which I found at Gulnarber Station, near St. George, on the Balonne River. This was made considerably easier for me by the kind assistance of Mr. G. M. Kirk of Gulnarber Station. As regards this instance of natural, and in this case hereditary *atrichia universalis* among the Australian aboriginals, I will only remark that it forms an interesting antithesis to the well-known cases of excessive hypertrichosis.

With a view of pursuing comparative anatomical researches on the brain of the marsupials, I went to Pikedale, near Stanthorpe, where I succeeded during a stay of almost six weeks in acquiring for my cerebral investigations some material which is almost impossible to obtain in the cities, such as Brisbane or Sydney, and which, as I have learnt by my own experience, cannot be obtained even in the bush with great ease and quickness. I succeeded, however, in obtaining a number of brains of some species of the genera—Macropus, Osphranter, Halmaturus, Petrogale, Phascolarctos, as well as a few brains of Ornithorhynchus and Echidna.

At the end of December last year, still availing myself of the kind hospitality of Mr. Donald Gunn, I went on to his other station, Clairvaul, near Glen Innes, with the intention of collecting some fossils, and without great trouble I got a series of interesting remains of *Diprotodon Australis*, *Nototherium Mitchellii*, *Phascolomys gigas*, *Macropus titan*, &c., &c.

When I received in May, 1880, in Thursday Island, a letter from my friend Mr. William Haswell, informing me that the Zoological Station in Sydney was not established, I determined not to leave Australia before the scheme had been carried out. Detained in Queensland by the work already referred to, I only arrived in Sydney in January of this year, and now, after a stay of one month, I have the pleasure to announce that I have every reason to believe that the Zoological Station at Watson's Bay will be opened in a short time. My stay in Brisbane has once more caused me to feel the *necessity* of such an institution for the biologist. I could expatiate at length on the advantages of a zoological station, but I content myself with remarking that, in spite of my great dislike to waste my time, I was obliged to spend many days, even weeks, in Brisbane and Sydney without the possibility of working, on account of the want of a suitable place.

I repeat again my conviction, grounded on long experience, that "the immediate need is not of apparatus or libraries, but of a place for undisturbed work."[1] I hope to be able, not later than in two months, to work in the Zoological Station in Watson's Bay. I am convinced that many men of science will avail themselves of it in future years; and I am satisfied to leave for future generations such a memento of my stay in Sydney as the first zoological station in Australia.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIGE.—The Physiological Laboratory (Dr. Foster's) will be open during the Long Vacation, and a series of repetitions of lectures and demonstrations will be given by Mr. Waters, the Assistant Demonstrator, in Elementary Biology, Histology, and Physiology.

The Cavendish Laboratory will be open during July and August, and the Professor of Experimental Physics or one of the Demonstrators will attend daily.

Prof. A. C. Haddon, of the Royal College of Science, Dublin, has been nominated by the Board of Natural Science Studies to study at the Zoological Station at Naples during the ensuing autumn.

The Board of Mathematical Studies has issued a report showing that in the last Mathematical Tripos the total of marks was 33,541, of which the first ten wranglers averaged 8582. In the last five days 11,753 marks were assigned to riders, and 7770 to problems; of which the first ten wranglers averaged 2388 and 936 respectively. The additional examiner stated his satisfaction with the answering; and he considered that much of the time formerly occupied by the study of astronomy, including the Lunar and Planetary Theories, Figure of the Earth, and Precession of Nutation, was now devoted to Heat, Electricity, and Magnetism. Comparing the progressive nature of the latter subjects with the stationary nature of the former, the latter afford the best means of testing the mathematical ability of the candidates.

Prof. Cayley will lecture in Michaelmas Term on Abel's Theorem; Dr. Ferrers (Master of Caius) on the Theory of the Potential; Mr. Niven (Trinity) on Electrostatics; Mr. Glaisher (Trinity) on Definite Integrals and Differential Equations; Mr. Hobson (Christ's) on Rigid Dynamics; Mr. Stearn (King's) on Conduction of Heat and Electricity; Mr. Allen (St. Peter's) on Magnetism; Mr. Dickson on Dynamics of a Particle.

The annual report of Prof. Adams to the Observatory Syndicate states that, notwithstanding the exceptionally unfavourable weather for observing, there had been made 2834 determinations of Right Ascension and North Polar Distance with the transit circle, including 2151 observations of zone stars which were made on eighty nights. Satisfactory observations of the partial solar eclipse, December 31, 1880, were obtained with the Northumberland equatorial, employing the wire micrometer. The observations with the transit circle for nadir point and level have been facilitated and rendered much more satisfactory by an alteration in the mode of illumination of the wires through the Bohnenberger eyepiece. Instead of placing a small hand-lamp on a stand close to the eyepiece, which gave an uncertain image at the best, the illumination is now effected by means of a paraffin lamp placed on a platform at the requisite elevation about ten feet from the eyepiece. The rays for the lamp are rendered parallel by passing through the system of lenses intended for the illumination of the microscopes of the eastern circle, which is not in ordinary use. There is now no difficulty in getting the light properly directed, and the images both of the Right Ascension and Declination wires are dark and very distinct. The observations of standard stars are completely reduced in R.A. and N.P.D. to the end of 1879 and part of 1880, as to the zone stars, the true R.A. and N.P.D. are obtained to the end of 1878, the approximate N.P.D. to the end of 1879. The calculation of reduction of apparent place to mean is completed to the end of 1876, and is far advanced for 1877. Meteorological observations are regularly made. A third assistant in the Observatory is urgently needed.

The following awards have been made by the Master and Seniors of St. John's College for proficiency in Natural Sciences:—To Samways, a Wright's Prize, with 100*l.* for the year; to Weldon, Edmunds, Love, T. Roberts, Foundation Scholarships; to Pagan, Goodman, Exhibitions. The Open Natural Science Exhibition was awarded to H. Wilson of the Leys School, and another Open Exhibition to J. Kerr of Manchester Grammar School.

SCIENTIFIC SERIALS

Trimen's Journal of Botany, June, 1881, contains:—Notes on *Carex flava*, L., by F. Townsend, M.A.—A revision of the Indian species of Leea, by C. B. Clarke, M.A.—Notes on Irish plants, by H. C. Hart, B.A.—Short notes.—Extracts and notices of books and memoirs.—Botanical notes.

THE *American Naturalist*, June, 1881, contains:—The archæology of Vermont, by Prof. Geo. H. Perkins.—On the larval habits of the Bombyliidæ, by C. V. Riley (with a coloured plate).—On the late explorations in the Gaboon, by H. von Kopenfels.—On the Pueblo pottery, by Edwin A. Barber.

Kosmos, Jahrgang v. Heft 2, contains:—Prof. Dr. Fritz Schultze, on the relations of sceptical naturalism to modern natural science, with especial reference to the evolution theory (conclusion).—Henry Potonié, on the relations of morphology to physiology.—Dr. Fritz Müller, *Atyoida Potimirim*, a mud-eating fresh-water shrimp (with twenty woodcuts).

[1] *Vide Proceedings* of the Linnean Society of New South Wales, August 26, 1878.

Revue Internationale des Sciences, May, 1881.—M. Debierre, on physical dynamism and biological dynamism (concluded).—A. Charpentier, on the examination of the powers of vision, from a general medical point of view.—J. Morton, the city of Gheel, in Belgium, and its asylums.—H. Müller, on the pretended refutation of Boumer of the theory of flowers (translated from *Kosmos*).

Nyt Magazin for Naturvidenskaberne, Christiania, 1880-1881. Band 26, Heft 1.—Herr Leonhard Stejneger continues his contributions to the ornithology of Madagascar, and describes a new *Tylas*, which appears to be closely allied to the *T. madagasc.* of Grandidier.—L. Meinich gives the result of his examination of the quartz and sandstone formations of the Trysilfjeld near Kongsberg, Norway, and Herr H. Rensch, editor of *Naturen*, describes the geological character of the strangely dislocated and fissured fjeld known as the Torghattee, on an island off the Heligoland coast. The same writer occupies nearly all the pages of Heft 2, first in giving the remainder of his observations of the Torghatten caverns and rocks, and next in a comprehensive and elaborate description of the character of the conglomerate sandstones and metamorphosed schists in the Nordfjord and Göndfjord districts near Berglun, to which he adds the analyses and histological results obtained from the examinations of these rocks in the Leipzig mineralogical laboratory. These numbers of the magazine contain, however, some specially interesting communications by Herren Danielssen and Koren of the various new forms of Gephyreæ and Echinodermata obtained in the Norwegian Arctic Expedition. These observers describe a form of Bonellia, to which they have given the name of *Hamingia Arctica*, which approximates closely to *Bonellia viridis*, first found in the northern seas about forty years ago by Herr Koren. Only one specimen was obtained of Hamingia. In regard to echinoderms the expedition has proved more fortunate, and Herren Danielssen and Koren describe several new forms of Asterias, Solaster, and Asterina.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, June 9.—S. Roberts, F.R.S., president, in the chair.—Prof. Mannheim and Mr. T. Craig (United States Coast Survey) were admitted into the Society, and Mr. G. R. Dick, Professor of Mathematics in the Royal College, Mauritius, was elected a member.—Much interest was excited at the meeting by the fact that one of the Society's Foreign Members was present, and proposed to read a paper. M. Mannheim is well known in this country to be a most elegant cultivator of the modern geometry on the lines of Poncelet and Chasles. He has more especially worked at the following subjects:—(1) The method of geometrical transformation, following out in this direction Poncelet's researches in the theory of reciprocal polars; (2) the plane representation of certain space-figures; (3) the wave surface (his early papers form the subject of an article in the *Quarterly Journal* for 1878 by Prof. C. Niven, F.R.S.); but lastly, he has been more particularly engaged upon the study of properties relative to the displacement of figures in space; to this he has given the name of "Géométrie Cinématique" (Dr. Ball in his "Theory of Screws" says, "To M. Mannheim belongs the credit of having been the first to study geometrically the kinematics of a constrained body from a perfectly general point of view"):—his recent work with this title has obtained a warm recognition *propter merita* in this country —on this occasion Prof. Mannheim communicated a paper "Sur les surfaces parallèles," which was characterised by all the clearness and power of exposition so well known to belong to mathematicians of the French school. Dr. Hirst, F.R.S., in proposing a vote of thanks, lightly touched upon the novelties of the communication, and expressed the pleasure it gave him and the meeting to see his fellow-student and friend present in the Society's rooms. A cordial vote of thanks having been carried, M. Mannheim briefly thanked the members present for their kind reception of him.—Other communications were:—On certain symbolic operators, by Mr. J. W. L. Glaisher, F.R.S.—On a system of co-ordinates, by Prof. Genese.—Note on a system of Cartesian ovals passing through four points on a circle, by Mr. R. A. Roberts.—On the Gaussian theory of surfaces, by Prof. Cayley, F.R.S.—On a theorem in the calculus of operations, by Mr. J. J. Walker.—On spherical quartics, with a quadruple cyclic arc and a triple focus, by Mr. H. M. Jeffery, F.R.S.—Note on the wave surface, by Prof. Mannheim.

Chemical Society, June 2.—Prof. Roscoe, president, in the chair.—It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society (June 16).—The following papers were read:—Experimental researches on the amalgamation of silver ores, by C. Rammelsberg.—On the action of solvents on saponified oils and waxes, by A. H. Allen and W. Thomson. The authors have made many experiments with a view of discovering a correct method for the analysis of mixtures of hydrocarbons with animal and vegetable fatty matters. Two methods are suggested. In both, the sample is boiled with a solution of caustic soda in alcohol, which is, in one case, diluted with water, and then shaken up with ether, to dissolve out the unsaponifiable matter, leaving the soap in the solution; in the other method alcohol is added to the mixture, and then some sodium bicarbonate and ignited sand; the whole is dried and extracted by petroleum spirit in a Soxhettes apparatus. Some analyses are given in the paper; good results were obtained.—On the sulphides of copper and a determination of their molecular weight, by S. U. Pickering. The author has heated cupric sulphide alone, in a current of hydrogen and in a current of carbonic acid, and concludes that the sulphur is given off in two separate and equal portions at totally different temperatures; therefore the molecule contains two atoms of sulphur. Hydrogen reduced the sulphide to the metallic state.—Chemical examination of the Buxton thermal water, by J. C. Thresh. The author has disproved the extraordinary statements of Playfair and Muspratt that one gallon of this water contains 206 and 504 cubic inches of nitrogen. The water really contains 22·98 c.c. of nitrogen per litre. He points out how the error originated. A complete analysis of the mineral constituents is given; amongst them are molybdic acid, cobalt oxide, &c.—On potable waters; determination of total solids, by E. J. Mills. This determination is made by carefully noting the time required by a glass bulb to rise a given distance through the water.—On the estimation of the value of zinc powder and on a gauge for measuring the volume of gases without calculation for temperature and pressure, by J. Barnes.

Zoological Society, June 7.—Prof. W. H. Flower, LL.D., F.R.S., president, in the chair.—The Secretary called the attention of the meeting to the opening of the Insectarium in the Society's Gardens, which had taken place on April 25, and read a report on the insects that had been reared and exhibited there, drawn up by Mr. W. Watkins, the Superintending Entomologist.—Mr. F. M. Balfour, F.Z.S., read a paper on the development of the skeleton of the paired fins of Elasmobranchs considered in relation to its bearings on the nature of the limbs of the Vertebrata. The object of the investigations recorded in this paper was explained by the author to be twofold—viz., on the one hand to test how far the study of the development of the skeleton of the fins supported the view which had previously been arrived at by the author, to the effect that the paired fins were the specialised and highly-developed remnants of a once continuous lateral fin on each side, and on the other to decide between the views of Gegenbaur and Huxley and Thacker and Mivart as to the primitive type of fin-skeleton. The author pointed out that the results of his researches were entirely favourable to the view that the paired fins were structures of the same nature as the unpaired, and that they gave a general support to the views of Thacker and Mivart. They clearly showed that the pelvic fins retain more primitive character than the pectoral. Conclusions were drawn somewhat adverse to the views recently put forward on the structure of the fin by Gegenbaur and Huxley, both of whom considered the primitive type of fin to be most nearly retained in *Ceratodus*, and to consist of a central multisegmented axis with numerous rays on its two sides. It appeared, in fact, that the development of the skeleton demonstrates that a biserial type of fin like that of *Ceratodus* could not have been primitive, but that it must have been secondarily derived from a uniserial type, by the primitive bar along the base of the fin (the *basipterygium*) being rotated outwards, and a second set of rays being developed on its posterior border.—Mr. W. T. Blanford, F.Z.S., read some notes on a collection of Persian reptiles recently added to the British Museum, amongst which was an example of a new species of lizard, proposed to be called *Agama Persica*.—A communication was read from the Rev. O. P. Cambridge, C.M.Z.S., on a new spider of the family *Theraphosidæ*. The chief interest attaching to this spider was the fact that it had lived in the Gardens of the Society from March to October, 1880. Mr. Cambridge proposed to name the species *Homœomma Stradlingii*, after Dr. Stradling, who had brought the specimen

in question home from Bahia.—Mr. G. E. Dobson, C.M.Z.S., read a paper on the pharynx, larynx, and hyoid bones in the *Epomophori*, indicating some very remarkable peculiarities of structure, in which these bats appear to differ not only from all other Chiroptera, but from all other mammals. Pharyngeal air-sacs were also described in the males of *Epomophori monstrosus, franqueti*, and *comptus*.—Mr. J. Gwyn Jeffreys, F.R.S., read the third of the series of his memoirs on the Mollusca procured during the *Lightning* and *Porcupine* expeditions, 1868-70. The present paper contained an account of the families from *Kelliidæ* to *Tellinidæ*. Eleven new or hitherto unfigured species were described. The geographical, hydrographical, and geological distribution of the species enumerated were fully given.—Mr. F. C. Selous read a paper on the South African Rhinoceroses, based upon specimens collected and observations made during nine years' hunting in Southern and South-Central Africa. Mr. Selous had come to the conclusion that in these countries only two well-marked species of *Rhinoceros* existed—namely, the square-mouthed *Rhinoceros simus*, and the prehensile-lipped *R. bicornis*.

Entomological Society, June 1.—Mr. H. T. Stainton, president, in the chair.—Rev. E. N. Bloomfield, M.A., was elected a Subscriber to the Society.—Mr. J. Jenner Weir, on behalf of Mr. J. W. Douglas, exhibited, and read remarks on, various British species of *Aleurodes* and *Orthezia*, one of which was described as new to science under the name of *O. Normani*.—Mr. T. R. Billups exhibited specimens of *Crabro clavipes*, L., and *Molorchus minor*, L.—Mr. J. Sang exhibited some interesting varieties, &c., of British *Lepidoptera*.—The Secretary read a communication from Mr. G. E. Piercey respecting a creature stated to be noxious to travellers in Turkestan. It was suggested that this was probably identical with the well-known *Argas Persicus*.—The Secretary also read a report from the Committee appointed at the last meeting of the Society to inquire into the supposed presence of *Phylloxera* on the vines in Victoria; also a communication from the Colonial Office respecting an insect stated to be destructive to the eggs of locusts in the Troad.—Lord Walsingham read a paper on the *Tortricidæ*, *Tineidæ*, and *Pterophoridæ* of South Africa.—Mr. A. G. Butler communicated a memoir on the genus *Sypna*.—Mr. W. L. Distant communicated descriptions of *Rhynchota* from the Australian and Pacific regions.

PARIS

Academy of Sciences, June 6.—M. Wurtz in the chair.—The Secretary read telegrams from the Emperor of Brazil (of May 31 and June 2) announcing the discovery of a comet.—On the right ascensions of the moon observed at Algiers by M. Trepied, by M. Faye. Hansen's tables, defective for long-period inequalities, are shown to be perfect for ordinary inequalities. Newcomb's correction, instead of being too great, has to be increased 1″.—Researches on sulphide of nitrogen, by MM. Berthelot and Vielle. *Inter alia*, it detonates with violence under the hammer, but it is less sensible to shock than fulminate of mercury or nitrate of diazobenzol. In heating, it deflagrates about 207°. The heat of formation is negative. The pressures arising from explosion in a closed vessel are very near those from fulminate, but the velocity of decomposition is very different.—On the report of M. Roudaire, on his last expedition in the Tunisian Chotts, by M. de Lesseps. Further examination confirms the feasibility of the inland sea project, the political advantages of which (with others) are noted.—On the geological results of M. Roudaire's mission, by M. Hébert. Tunisia seems to have emerged during the long periods between the deposit of the Senonian Chalk and that of the Middle Miocene. The basin of the Chotts, with the Cretacean masses bordering it on either side (their strata anticlinal), are like a button-hole, the Chotts forming the aperture.—New analyses of jadéite and some sodiferous rocks, by M. d'Amour. It is proved that beds of jadeite (which is largely used in India and China for ornaments, and found in the form of coins, hatchets, &c., in European dolmens and caves), exist in Asia, especially the Thibet region; also in North and South America. From analysis of some European rocks the author finds reason to suppose that beds of jadeite may also be found in the Alpine chain, or region near; thus the prehistoric articles in Europe would be naturally explained, without migration of Asiatic peoples. MM. Boussingault and Daubrée made remarks on the subject.—Study of electricity on board modern ships; incidental remarks (1) on the influence of the mode of junction in complex electric circuits, and (2) on the principle of an electric hygrometer and a fire-alarm, by M. Ledieu. The iron hulls of fast ships, sheathed with wood, then copper, both fixed metallically, form a complex pile, which the author studied. Experimenting with a moist piece of wood having copper nails in it, he found a battery current had much greater intensity when the rheophores were applied to the nails than when applied to the wood. Using dry wood with the former arrangement, the intensity varied with the atmospheric moisture. This might be applied *e.g.* in measuring dew-formation. For a fire-alarm he would keep the wood slightly moist by means of spongy matter on its surface connected with water. A galvanometer would indicate the degree of dryness of the wood, and if a certain limit were reached the needle would cause a bell to ring.—On the *rôle* of phosphoric acid in volcanic soils, by M. de Gasparin. He controverts Prof. Ricciardi's view that the fertility of the eruptive strata of Etna is due to presence of this mineral. The concomitance of muddy formations, and the climate, hastening the decomposition of lava, are the chief factors.—The vines of Soudan of the late M. Légard, by M. Planchon.—The solar parallax deduced from American photographs of the transit of Venus of 1874, by Mr. Todd.—On the functions of two variables arising from the inversion of integrals of two given functions, by M. Fuchs.—On the expressions of co-ordinates of an algebraic curve by Fuchsian functions of a parameter, by M. Picard.—On a property of uniform functions, by M. Poincaré.—On the liquid state and the gaseous state, by Mr. Hannay. He claims to have proved, more than a year before, for all pressures, what MM. Cailletet and Hautefeuille have lately established for a single pressure: viz., that the continuity of the liquid and gaseous states (Andrews) is only apparent.—Cyanides of sodium and barium, by M. Joannès.—On the combinations of iodide of lead with alkaline iodides, by M. Ditte.—On the *rôle* and the origin of certain microzymas, by M. Béchamp. The microzymas in rocks, earth, mould, street-dust, or the slime of marshes, have no other origin than those forming an integral part of every living organism, and whose *rôle* is the total destruction of this after death; after which they remain in the soil or the air, ready chiefly for transformation of organic matter for vegetation.—On the non-existence of *Microzyma Cretæ*; reply to M. Béchamp, by MM. Chamberland and Roux.—On the mechanism of troubles produced by cortical lesions, by M. Couty. Unilateral and limited cortical lesions involve profound modifications of the various functions of the medulla oblongata and the spinal cord opposite, leaving intact the brain-functions.—On the embryogeny of Ascidians of the genus *Lithonephora*, by M. Giard.—On the stomatorrhiza of *Succulina carcini*, Thompson, by M. Jourdain.—On the morphology of the fœtal envelopes of Chiroptera, by M. Robin.—Contributions to the cryptogamic flora of Banks's Peninsula (New Zealand), by M. Crié.—Mr. Stone's star-catalogue was presented by M. d'Abbadie.

LECTURES ON TEACHING

Lectures on Teaching, Delivered in the University of Cambridge during the Lent Term, 1880. By J. G. Fitch, M.A. (Cambridge: University Press, 1881.)

OUR review of this new contribution to the now copious and increasing educational literature of the country has been delayed by causes complimentary to its author. The felicity and charm of the style, the freshness of treatment of even hackneyed topics, and the interest and practicalness of the matter, rendered the reviewer's proverbial dipping into a book impossible in this case, and the work had to be read for its own sake as much as for that of criticism. The author has long been known as one of our most earnest practical and enlightened educationists, and though perhaps not a polemical pioneer in the educational field, an advanced, safe, and healthy thinker on the important problems involved. Of this new utterance of her husband, the *uxor dilectissima*, to whom the book is curiously but most appropriately dedicated, has no reason to be ashamed, even though it is not the newest poem or novel, and only a prosaic, but by no means prosy, volume of "Lectures on Teaching"—a title, by the way, much too modest for the quality of the book, which should in future editions be exchanged for one more worthily distinctive and more expressive of its contents.

The occasion of its production is one of no small interest and importance in the history of educational progress in this country. For some years back, there have been made some laudable attempts to secure for education University recognition and standing, by the appointment of Professors of Education. The first practical effort in this direction was made by the College of Preceptors, which had the merit of appointing, in 1873, the first Professor of Education in Britain, the late enthusiastic and enlightened Joseph Payne. This was followed by the establishment of Education Chairs, in 1874, in the Universities of Edinburgh and St. Andrews. It took some time for our greater conservative Universities to adopt, even in part, such an unwonted innovation, though earnestly and repeatedly pressed to do so in Memorials from the Head-masters of our great Public schools, whom they had trained as scholars but neglected as teachers; leaving them to gain what professional skill they have, as they themselves confess, at the expense of their pupils. At length, in 1879, Cambridge came to the conclusion that it would no longer be derogatory to them to patronise to some extent the new Science of Education; and a "Teachers' Training Syndicate" was appointed, which issued a scheme of examination in the history, theory, and practice of education, with lectureships on these branches of the subject. The first course was given by the well-known genial educationist, Mr. Quick, on its history; the second, by Mr. James Ward, on its science; and the third, by Mr. Fitch, on its practical aspects, which we have now before us. The next step for these Universities to take, which they must—shall we say cordially will?—take before very long, will be to do for education what has been done for other subjects—to give it full University status by the appointment of Professors of Education—a step that will do more than aught yet attempted to give teaching and teachers the standing, influence, and emolument to which the importance of their work to national culture and progress justly entitle them from the lowest to the highest; and a step that will more than repay the Universities themselves, which would thus be entering, as Mr. Fitch well observes, "on an honourable and most promising field of public usefulness," that will help to "make the work of honest learning and of noble teaching simpler, more effective, and more delightful to the coming generations."

Though deprecating any claim to be a systematic treatise, or a "manual of method" on the subject, the book traverses the greater part of the general field of inquiry, and to the practical student and teacher will be found more helpful, suggestive, and scientific than more elaborate and pretentious text-books. The work is singularly readable, attractive, sound, sensible, and practical, and altogether free from hobby-horsiness. Though subordinating theoretical treatment, Mr. Fitch is, as a rule, scientific in spirit and suggestion; and when discussing, as he does, controverted questions that generally rouse polemical combativeness, if not bitterness, he does this with so much of the *suaviter*, and with such genial persuasiveness in favour of his conclusions, which are for the most part sound and abreast of recent opinion, that the book is calculated, in an unusual degree, to carry enlightened conviction on many problems into the conservative ranks of University men, still too impervious to change in their traditional views of education. Canvassing, as Mr. Fitch does, so many subjects of controversy, it cannot be expected that his conclusions will be generally accepted—on not a few we deem him in error, and should be prepared to join issue; but they are always so presented as to command, and to gain, the most careful consideration and to disarm opposition—an invaluable element with the class he specially addresses.

The mere headings of the chapters show the interest and extent of the field traversed. We have "The Teacher and his Assistants," in which an inspiring, noble, but far from Utopian, ideal is held up for imitation: "The School, its Aims and Organisation," in which such important questions, as what a liberal education is, what subjects should be taught, and the like, are discussed: "The School-room and its Appliances," where excellent practical suggestions are given towards making our schools the healthy, comely, and educative centres they ought to be in any wise community: "Discipline," in which this vital element in school life is treated with admirable spirit and wise counsel, traversing the various disciplinary influences that ought to be brought to bear on the child, before the *ultima ratio* of corporal punishment is resorted to, which, though not condemning it altogether, he wisely thinks "is almost wholly unnecessary, does more harm than good, and in just the proportion in which teachers understand their business, they will learn to dispense with": "Learning and Remembering," where some sensible practical hints are given as to the use and abuse of that universal school hack, the memory, the treatment of which he rightly considers a very good test of "the difference between skilled and unskilled teaching," though his psychology of this so-called faculty is questionable, savouring

too much of the orthodox Hamiltonian school, and too little of the, at present despised, phrenological, which latter considers memory a mode of action of all the intellectual faculties, and which, on this point at least, contains more truth and practical suggestion than is generally suspected: "Examining," in which the elements of skilful questioning are well put, and not a few fresh suggestions made, as in regard to the use of "Socratic questioning" in school, on which, however, we recommend to the author's consideration, the views of his friend, William Ellis, the liberal and philanthropic founder of the Birkbeck Schools, who was the first to adopt and advocate it in its entirety, making it a true Socratic *dialogue, the pupil also stating difficulties and asking questions of the teacher*, as well as answering questions asked: the "Preparatory Training" of the child, in which much sound practical advice is conveyed as to the early stages of the "three R's" and their congeners, but in which, amidst much appreciation of the Kindergarten, this system is on many points—we are sure unconsciously—greatly misunderstood and misrepresented; as that Fröbel did not take "a large, or very sound, view of the purpose of education as a whole," that the system "does little or nothing to encourage reflection," is "apt to mistake means for ends," "does not train to overcome difficulties," and much else in the same strain, regarding which, we may safely and confidently leave Mr. Fitch to Miss Shireff and other wise and fully-informed *Kindergartener*: "The Study of Languages," in which the vexed question of the place of the ancient classics and modern languages in education is very fairly and estimatively stated, and recent broader views advocated, a chapter that would be studied with advantage by both parties in this wordy strife: "The English Language," where he claims a very high—we should be inclined to claim even a higher—place for the native tongue and literature, in intellectual, cultural, and general educative power, when rightly taught, and gives some excellent practical suggestions to help towards this, his conclusion being admirably expressed thus—"If your scholars do not acquire a positive love for reading; if they do not ask to be allowed to read the whole book or poem of which the extract you take as a lesson forms a part; . . . if they do not feel a heightened admiration for what is noblest and truest in literature, and an increasing distaste for what is poor and flimsy and sensational: then be sure that there must be something incurably wrong in your method of teaching, and that all your apparatus of grammar, paraphrase, and logical and grammatical analysis, will have failed to fulfil its purpose."

Then we have two chapters on "Arithmetic," both as an art and a science, on which, as might be expected from the author of a well-known text-book on the subject, he places high value, for both culture and use, and on which he gives very good hints; on "Geography" and "History" he is equally fresh, suggestive, and practical; and the book concludes with two very good chapters on the teaching of "Natural Science" and on "The Correlation of Studies."

On the place of science and scientific teaching in all true education Mr. Fitch speaks with his accustomed candour, fairness, and perspicuity, and pleads in their favour with a quiet but firm and skilled advocacy, which, with its genial non-polemical incisiveness and force, makes it a real acquisition to the growing literature on the scientific side, which will carry conviction into certain scholastic circles that would be, as they have been, deaf to more formal and strenuous pleading. Here Mr. Fitch reveals himself with unwonted power as a skilled, Socratic, but disguised polemic, in the advancing cause of science in education. His way of making the scientist in education put his case "to those who live in the academic world," is admirable: "You are mistaken in supposing that the domain of physical science is a merely material and practical region, while yours is essentially intellectual. There is here a body of truth of the highest practical utility, no doubt, but also of the greatest value for educational purposes. The laws and principles by which the facts of the material world may be explained and co-ordinated, are quite as uniform, quite as beautiful, and as far-reaching in their applications, as any of the laws of language or the truths of mathematics. Moreover, the processes of thought required in the study of these questions are just as vigorous, just as stimulating, stand in just as close a relation to the intellectual needs of a well-instructed man, as those involved in the older studies. You can make the teaching of physical science as fruitful, as thoroughly disciplinal for all the higher purposes contemplated in a liberal education, as the teaching of Greek or of geometry, if you will only first recognise the possibility of making it so, if you will encourage skilled and accomplished men to take up this branch of instruction, and are ready to give them the same status and encouragement as you now give to accomplished teachers of philology or history. Enlarge your conception of what a liberal education means." Mr. Fitch concludes that "of the legitimacy of these claims there can be no doubt," and wishes "some Huxley or Tyndall had enunciated this message before we ourselves went to school." He shortly discusses the utilities of physical truths, their beauty and intellectual attractiveness; the disciplinal value of the inductive process by which they are discovered, and its function as an invaluable corrective and necessary supplement to the one-sided deductive method of the common scholastic studies. His recommendations on the practical teaching of science in schools, and on technical education, are also good, and to the point. Altogether, this chapter on Science deserves perusal by all interested in its teaching, and we wish our space allowed us to take his arguments up in detail.

The last chapter, on "The Correlation of Studies," is an important one, and in great part sound and sensible, though not a few will be inclined to disagree with the author on some points; for the problem of "the conflict of studies" is as yet more crude and unsettled than any other in the educational world. He wisely controverts the plausible maxim, *non multa, sed multum*. His division of the proportionate times that should be given to the different classes of studies, viz. "nearly half to language and literature and subsidiary exercises, and of the remaining half, rather the larger portion to mathematics, and the smaller to experimental science," will provoke controversy, and is surprising in an advocate of science in schools. He would also have never more than two physical sciences studied at the same time. His remarks on the principle of selection amidst the increasing press of studies should be serviceable to distracted teachers, and help them to a

choice; though here, also, he leans overmuch to the linguistic side.

In the curriculum of studies recommended by him, Mr. Fitch has strangely subordinated, if he has not greatly ignored, the studies that prepare the citizen for his duties as a member of the State—the Social and Political Sciences. Surely he has not read, or greatly studied, the admirable pleading in their favour to be found in the works of his friend William Ellis, and also of George Combe, as recently fully presented in his educational contributions, edited by one of his colleagues in the inspectorate. In this respect, there appears to us to exist a serious hiatus in his plan of study. One of the doctrines he enunciates is also enough to raise the old phrenologist from his grave, what he calls "the convertibility of intellectual forces," whereby, he informs us, "every kind of mental power, once worked and applied to a worthy purpose, becomes available for other purposes, and *is capable of being transformed into power of another kind*"—an ancient error in schools, still fruitful of failure and wrong, which we are surprised to find held by a man so generally wise on education. Poor George Combe otherwise fares sadly at the hands of Mr. Fitch, who describes his mission in life as being that of advocating the one doctrine of inherent hereditary aptitudes, and says that "he never could induce his friends seriously to attempt the classification and teaching of a school on his principles, and the experiment yet remains untried"! What of the history of such schools given in the work on Combe's principles just named?

Though not agreeing on many points with the author, as was inevitable in a field so full of controversial matter as the growing science of education, we look upon the book as a valuable contribution to the subject, which, by its unusually attractive style and high tone, will command a wide audience, and, from the auspices under which it is produced, will reach places where sound educational philosophy too seldom penetrates. We cordially recommend it to all interested in education, and specially to teachers; and also to the active Education Society, as, like Prof. Bain's recent work on Education, which they have already taken up, an admirable basis of profitable discussion.

PRACTICAL HISTOLOGY

A Text-Book of Practical Histology, with Outline Plates. By W. Stirling, M.D., Sc.D., F.R.S.E., Regius Professor of the Institutes of Medicine in the University of Aberdeen. (London: Smith, Elder and Co., 1881.)

AT the outset Dr. Stirling informs us that "the purpose of this work is twofold: first, to give plain, definite, and precise directions for the preparation and examination of the animal tissues; and secondly, to ensure that the student executes a drawing of the majority of the microscopic specimens which he makes for preservation. For this purpose a series of Outline Plates is issued with the text."

As regards the first of these objects, there is no doubt that to give "plain, definite, and precise directions" is a desirable and praiseworthy object, which most, if not all "practical" books strive to attain. Those that succeed in this endeavour differ from one another chiefly in the means by which this object is accomplished; in some the author arrives at his object after long-continued patient and diligent work, in other rarer instances he utilises the works of others, and by doing so he may, and sometimes actually does, produce a book which has considerable merits of its own, inasmuch as it gives in plain and simple words valuable and useful extracts of much larger original works full of minute and bewildering details, not easily understood by, and of little practical use to the ordinary student. Dr. Stirling, although his book cannot in any sense claim to be considered other than a book of compilation, has nevertheless succeeded in presenting to the medical student, anxious to acquire the necessary amount of knowledge in practical histology, a work which, conveying in a short and intelligible manner a great deal of information, will, we doubt not, prove of service.

As regards the second object of the book, viz. that the student should for himself make drawings of his microscopic specimens, we fail to see how Dr. Stirling's Outline Plates can advance this object in a satisfactory manner. We always thought that the student drawing the correct outlines of the specimens or of parts of the specimens prepared by himself, has got everything that is essential to guide him in the study of those specimens. To fill in the details in pencil, or, as Dr. Stirling suggests, and what is still more laborious, in colours, in the outline figures drawn for him from somebody else's specimens, appears to us of more than questionable value.

Besides the directions for practical work a considerable part of the book is taken up by the description of the structure of the simple tissues and organs. As far as we can see, these descriptions are in a great measure, to the extent of verbal quotations, borrowed from other books, without even an attempt to mention this fact; by doing so Dr. Stirling has deviated from the accustomed rule, and has proceeded in a rare and unexpected manner. If an author introduces abstracts and verbal quotations from any other work, we believe it will be universally admitted that whatever the aim and nature of the book, the author is bound to mention his source; if he omits to do this, intentionally or unintentionally, he lays himself open to the charge of having committed what in the eyes of every right-thinking man, not to say of every man of science and teacher in a responsible position, must ever be considered a grave offence.

Dr. Stirling has made very extensive use of the "Atlas of Histology" in some chapters, *e.g.* on the salivary glands, the kidneys, the generative organs, and others, making copious extracts therefrom, to the extent of verbal quotations, without in any way indicating that he has done so.

Dr. Stirling's proceeding is greatly to be regretted, since by his numerous and original works in histology he has won the esteem of his *confrères* and has proved himself to be sincerely anxious about the promotion of this science.

The publishers deserve great credit for the handsome style in which the book is brought out.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Electric Railway in Paris

I HAVE within the last few days received a letter from a friend in Paris, who writes that he had last week travelled on the electric railway in that city. There is still much, he adds, to be done before it can be brought into general use; but nevertheless the train moved satisfactorily. There were fifty-four passengers in the carriage, which was propelled by a large Gramme machine and 160 cells of Faure's battery. The experiments are to be recommenced very shortly with a new motor by M. de Méritens, and a Faure's battery. W. SPOTTISWOODE

41, Grosvenor Place, S.W., June 16

Probably New Variable and Red Star

ON May 22 I found, 2° 51′·7 north of α Cygni, a deep red or crimson star, which is not in the Bonn Catalogue. The nearest to it there is + 47° 3167, which in declination corresponds with a white star that I observed at the same time, but not in R.A.

Dr. Doberck writes to me as follows:—"Markree Observatory, 1881, May 29; observed the *new* star; brick-red, the nicest I ever saw, 8·7 mag."; and "1881, May 31: 1h. a.m., colour same as before; 8·4 m."

Mr. Ward of Belfast, who observed in the early morning of May 31 in strong twilight, describes the star as "deep crimson; beautiful object; two or three comites."

Mr. Gledhill, in Mr. Crossley's observatory, Halifax, found it, on May 30, "strikingly red."

Dr. Ball, the Astronomer-Royal for Ireland, observing at Dunsink, saw it "a superb crimson."

Prof. Krueger, director of the Kiel Observatory, described it as "*auffallend roth*" (remarkably red), on May 30.

On June 2 it appeared to me unchanged in colour, and increased from 9 mag. to 8·4.—June 7 and 8, colour still the same, and 8·3 or 8·4 magnitude.

Dr. H. Kreutz, writing from the Bonn Observatory, states that he finds an observation of the star recorded on June 19, 1857, but not at any other time during the progress of the observations for the Bonn Catalogue, in which it has not been published. There does not appear to be any note of its colour, and I think it will most likely prove a variable of a very remarkable character. Prof. Krueger makes its position for 1855 = α 20h. 36m. 37s.·9; δ 47° 37′ 33″. Herr Kreutz's position is α 20h. 36m. 37s.·0; δ 47° 37′·9. The white star mentioned above is not recorded in any of the Bonn observations; and, on the other hand, I may add that I do not identify + 47° 3167 in the telescope. I estimated the white star at about 9·5 mag. of Argelander's scale, and therefore within the limits of the *Durchmusterung*.

The small stars seen by Mr. Ward are perhaps too distant to be strictly considered as comites to the red star. They are sufficiently difficult to me, though probably easy to his well-known extraordinary sight. The position of the nearest that I see is about 0°, and I find two others more distant—one at 350°, and one at 110°, with a power of 120° on a 4½ inch O.G.

There seems a peculiar dimness about the star, referable, probably, to the dark shade of its red. An uneducated person with a very excellent eye, and who never heard a description of a red star, compared it, at first view, to "a drop of *black* blood." It may be conveniently and well compared with Nos. 448 and 553 of my "Red Star Catalogue," especially with the former, the colour of which was described by Secchi as "intense"; and in the glowing red of the one object will be remarked a striking contrast with the deep sombre tint of the other.

I make the approximate positions of the red and the white stars for 1855, and corrected from my first observations, as follows:—

	h.	m.	s.	°	′
The red	20	36	27	+ 47	37·5
The white	20	36	18	+ 47	46·8
Argelander's position of his + 47° 3167	20	36	28	+ 47	46·8

Millbrook, Tuam, June 3 JOHN BIRMINGHAM

The Doctrine of the Conservation of Electricity

I WISH to take the earliest opportunity of responding to the courteous letter of M. Lippmann, which appears in the current issue of NATURE, with the acknowledgment that his quotation from the *Comptes rendus* of 1876 establishes in the most conclusive manner his priority of date in the enunciation of the doctrine of the *Conservation of Electricity*. As to my own independent enunciation of this doctrine, it was arrived at without any knowledge of the comparison drawn by M. Lippmann in 1876 between the cyclical flow of heat (of Carnot's theorem) and the cyclical flow of electricity. I approached the matter upon somewhat different and less clearly defined lines, and finally struck upon the fundamental notion of the Conservation of Electricity when endeavouring to think out the relations between electromotive and ponderomotive force in an electric theory of radiation based upon Clerk-Maxwell's Electromagnetic Theory of Light. My speculations on this point were committed to writing some weeks ago, and will shortly be published. I content myself in the meantime with pointing out how near Clerk-Maxwell came to a similar conclusion. In Article 35 of his well-known treatise, he says emphatically: "While admitting electricity, as we have now done, to the rank of a physical quantity, we must not too hastily assume that it is, or is not, a substance, or that it is, or is not, a form of energy, or that it belongs to any known category of physical quantities. All that we have hitherto proved is that *it cannot be created or annihilated*" (the italics are mine). Nevertheless the immediate and logical conclusion that electricity, like matter and like energy, is subject to a law of conservation, appears to have been rejected by Clerk-Maxwell for reasons explained in Article 574 of his treatise, consequent on his inability to discover whether an electric current possessed momentum or could exert a mechanical reaction upon the matter of the conductor through which it flows. The unfortunate dilemma which suggested this experiment could hardly have been raised if it had then been as clearly understood as it now is that there is the same distinction between electrokinetic and ponderokinetic energy as between electromotive and ponderomotive force. But to discuss this matter further would lead me to take up too much space.

Thought-Reading

IT would seem that the "discovery" of reading people's thoughts, lately mentioned in the daily papers, is in no way essentially different from the well-known "game" of "wishing" often played by young ladies. It consists of the following procedure. One person goes out of the room, while others arrange upon what she is to do. She enters blindfolded, and in the particular instance now alluded to, was turned round several times so as to be quite unconscious of the direction in which she was facing. Two persons now place their hands on either side of each shoulder, making their fingers meet at the back of the neck and under the chin; or they may be placed round the waist; but as the forehead appears to be equally sensitive, perhaps it is immaterial where the hands be situated. After standing still a moment or two, the lady moved slowly round in the direction of a sofa under the impression, as she afterwards said, that she was walking in quite another way. Having reached it, she sat down (not even knowing the sofa was close by), and deliberately put out her hand, took up an antimacassar which lay upon the sofa, and raised it, asking, "Is this what I was to do?" This was perfectly correct, the antimacassar having been expressly laid there for the purpose.

It was settled that another lady should walk into the conservatory. To do this she had to pull up a blind, lift an iron bar and open the shutters, then undo the glass door behind them which led into the conservatory. All this she did unhesitatingly, and walked straight into it. I could describe several other instances where ornaments and other things had to be selected out of various groups of objects, &c.: but the above will illustrate the process.

One essential condition of success is that the individual must voluntarily and entirely surrender the will, while those who hold the person blindfolded must *determine* as powerfully as they can that the latter shall do what they wish. Care should be taken not to *push* the individual in the desired direction. This however may be done involuntarily, but it will not account for the person doing all that has been previously determined after

arriving at the spot. Some ladies describe a remarkable sensation accompanying the process: a sort of "all-overishness," or even faintness, so much so that the lady first alluded to on one occasion staggered, and could not proceed at all.

It appears to me to be a very peculiar psychological phenomenon well worthy of investigation, if possible, but too well known to be disputed. GEORGE HENSLOW

6, Titchfield Terrace, Regent's Park, N.W.

P.S.—Since writing the above I have heard of a much more remarkable case than the preceding. The operators sat in a circle, silent, but determinately "willing" that a certain lady should do what they had resolved upon. She stood in the centre, and was not blindfolded or touched by any one. In every case she did it correctly. One thing that was agreed upon was for her to take a bottle of wine from one table, carry it to another, and pour out a definite quantity of wine. This she did, not exceeding the amount predetermined. On a second occasion she had to find a key hidden away behind some books. As she approached the place she became very excited and hysterical, but at once extracted the key.

The above cases clearly show that as far as they are concerned "thought reading" is an incorrect expression, as the person operated upon is a passive automaton, while others, as it were, force their wills upon her. "Will-imparting" would seem to be a better term.—G. H.

Notes of the Cuckoo

IN a letter appearing in NATURE, vol. xxii. p. 76, I stated that—"All the cuckoos here intone in a minor key except one, which alone does not flatten the 3rd of the tonic. The key is in all cases precisely D of concert pitch, as proved by a tuning-fork, and the first note is F on the fifth line." This year I find that, while the cuckoos here generally intone in D minor, as above, there is one again that intones in D major, and two others in C major and C minor respectively. Some that I casually heard in other places in the neighbourhood intoned in D minor.

Millbrook, Tuam, June 1 JOHN PIRMINGHAM

Notes on the Indian Glow-Fly

HAVING failed to find any critical description of these interesting insects, it is possible that the notes I am now able to send you may cause others to enter the field of inquiry. Situated some 2900 feet above the sea, and in Central Southern India amidst hills, valleys, and streams, I have had peculiar opportunities for observing them.

They are not to be seen during the daytime, but so soon as darkness steals upon twilight, so surely do these small natural lanterns become visible, and their numbers rapidly increase, much indeed as the visibility of the stars increases as the evening passes into midnight.

The fire-fly, when examined individually, is by no means a pretty-looking insect, and comparing it to other insects and flies, it is certainly both large and ungainly. An ordinary house fly is five-sixteenths of an inch in total length and weighs ·25 grains, but the subject of my notice has a total length of nine-sixteenths of an inch and weighs ·66 of a grain; we thus at once learn something as to his size and weight. The glow-fly—or beetle as I should term it—has a black head and antennæ; the thorax and abdomen are of a yellow-red colour. This latter part of the insect's body is divided into six rings, and, counting from the thorax, it is the fourth ring that emits the light. There is a rectangular opening in this ring which is merely covered by a very thin skin; it is in fact a *window* from which the light emerges. The insect has only one pair of wings: these are small, most delicate and thin, and are sheathed. It is worthy of careful notice that these insects fly both rapidly and slowly, but make no noise or buzz in the air. To test this further I have frequently liberated several of these glow-beetles in my bedroom, and in the dark they have only appeared as *fairy stars*, as no humming could be detected.

As regards the character and quantity of the light, I have to observe that one insect enables me to see the time by a white-faced watch when four inches distant; twelve of them placed in a glass jar enable me to read a book with ease, and are equal to a small Geissler's tube. The light is of an exceedingly beautiful colour—a sombre yellow tinged with green, but at intervals it is brilliant. A preliminary examination of the light in the spectroscope (a large one made for me by Browning) shows a distinct clear continuous spectrum, no lines or bands of any kind being visible.

The insect made to crawl on a card placed over the poles of a powerful compound permanent magnet showed no signs of uneasiness or change of light. Similarly placed over an electro-magnet (ten Grove cells) and rapidly alternating the current caused no change. Placed within a coil of covered wire, no change. Blowing very gently, my breath on the insect caused no change; this was also tried with a blowpipe. Cold air at 50° caused a distinct diminution of the light; on the other hand, air at 100° caused an increase of light.

I now placed several of the insects in a bell-jar, and gave them a good supply of clean oxygen gas; the luminosity at once increased fully 25 per cent. On a dead insect (which still sheds light) oxygen gave similar results, and on extracting the luminous part and blowing oxygen upon it the light was much increased.

It will prove interesting to mention that, so soon as darkness has fairly set in, millions of these insects invade the trees, and as my bungalow is near to a stream and level with the tops of the trees, I am able to notice them with much care. The curious pulsation or flashing of their light is remarkable: the insects resting on the tree all act in perfect concert, *i.e.* five seconds of no light, then seven rapid flashes; five seconds, no light, seven flashes; and so the game continues throughout the dark hours.

At first I had reason to believe that the insect when flying only emitted light; this however is not the case; for when observing the Pole Star for variation with my theodolite, it occurred to me during a passing cloud to turn a telescope on to the glowing tree. At once I had the field of view filled with tiny stars, but both fixed and wandering.

It is also worthy of special notice that all the glow-insects on a dozen or more trees will continue to keep up the most perfect time as to the flashing of their light and the interval of pause, and this for many consecutive hours; but this singular agreement as to the time relates to close clusters of trees only. Thus distinct groups of trees separated by one or more hundred yards may not agree, and do not do so as a rule.

I have been informed on safe authority that the Indian bottle-bird protects his nest at night by sticking several of these glow-beetles around the entrance by means of clay; and only a few days back an intimate friend of my own was watching three rats on a roof rafter of his bungalow when a glow-fly lodged very close to them; the rats immediately scampered off.

In conclusion, these insects see by day as well as by night, and I incline to the idea that the beautiful light they carry serves as a means of intimidation or protection, and certainly as a means whereby to recognise friends.

As I gaze from my verandah down the Nadgani Valley into the dark night I see the pulsations of light here, there, and everywhere! and as my optical powers increase so do these gaseous, nebulous patches become resolved into real living stars! H. A. SEVERN

Wynaad, India, May 5

Birds Suffering from Cold

THE unusually severe weather (5° – 12° Réaumur) of these last twelve days struck heavily on the swallows of our country. They have been found dead by hundreds. The distress of the poor animals must have been extreme. Suffering from hunger and cold, they pressed against the windows, and being brought in suffered to be petted and fed, but died from exhaustion. In Kopidlno about 300 took shelter under a balcony, and the cold growing more and more intense towards night, they clustered on each other like bees until morning, when thirty were found dead. I have been walking this afternoon in the suburbs of Prague, where a fortnight ago I have seen swallows skipping on the river and hunting in gardens, but although the weather was now clear and warm, I could not see a single one. Tidings of suffering swallows come from the country, where people have been kind to them, feeding them on ants' eggs and flies, but they would not eat, and died. In some nests the young ones were found starved alone, in others their mothers were with them. J. V. SLÁDEK

Prague, June 16

An Optical Illusion

THE illusion of the inverted pin was shown me about the year 1846-47, and I well remember, when I was at Cambridge,

working out the explanation inductively. In the autumn of 1847 I was spending an evening with Dr. P. M. Roget, at his house in Woburn Square, when among other subjects we conversed upon was that of optical illusions. The inverted pin was one of his illustrations, and I think he mentioned having explained it in some scientific serial.

Some years ago the late Mr. Becker, formerly scientific foreman to Messrs. Elliot Brothers, constructed for me a binocular apparatus for showing the union of two shadows, one on each retina. To my surprise I found the resulting phantom did not differ in position from the single shadow. C. M. INGLEBY

Athenæum Club

How to Prevent Drowning

I ONLY write in the interests of humanity. Let those who will go in for swimming, and I wish sincerely that every one could swim. Treading water however conducts at once to swimming. Every one can tread water who likes. It is just as easy, if we only knew it, to tread water as to tread the earth, and proximately just as safe. Men and women might walk into the deep sea and out again when they pleased. Nature has not been so niggard with us as some persons imagine. Why are we not as safe in water as is the dog? It is simply because he treads water, and we do not. As often as I chose to chuck my stick into the Causey surge my dog brought it out. I could have done the same; any one could do the same who chose. But assuredly I should have paddled water as the dog did. In treading water the body is erect, or nearly so; in swimming we sprawl, and are comparatively helpless. The admirals, both of them, have given valuable testimony as regards the efficacy of treading water. Before the present pier at the Cape was built, vessels in bad weather could not communicate with the shore, even by boats. Men, then, treading water amid the mountain seas, carried communications to and fro in oilskin caps. I have heard it was the same at Madras. Young Gordon, apprentice to the sea, fell into mid ocean while fisting a sail. The poor fellow's heart sank when he saw the ship sailing away. But, as he afterwards told me, he trod water, and kept up till the boat reached him. I have trodden water again and again with a big boy on my back. Any one might do the same. Not one woman in ten thousand, not one man in a thousand, I suppose, can swim. They do not know they can tread water when they fall in, and of course drown, as two fine young women who had got a little out of their depth in this place did last year. But ignorance and prejudice cannot always rule, and the day will surely come when human beings, better instructed, shall enjoy the same immunity in the water that other animal, not human beings, now enjoy. HENRY MACCORMAC

Bournemouth, June

Buoyancy of Bodies in Water

A propos of the question of drowning, as the same is now raised in NATURE, and especially so as to the alleged "fact that men are very different in buoyancy," allow me to say that when stationed many years ago at Pembroke Dock, South Wales, two soldiers were drowned there within a few days of each other. One of these casualties occurred off an island named the Stack Rock, in Milford Haven, that was garrisoned by invalided artillery, while the other took place in the creek that separates the town and dockyard from the huts. In the former instance the body of the (drowned) man remained floating upright in the water, "bobbing up and down with every wave"—as an eye-witness assured me—for a considerable time, or until it was lost to sight or recovered (I forget which just now). In the latter the body—that of a healthy, muscular man—was picked up a day or so afterwards by a passing boat as it was floating out with the tide to sea; and I have since seen several fresh bodies floating in the Ganges. Indeed the survivors always attach weights to the remains of even the poorest of their kindred ere they deposit them in that sacred stream; but this may be for the purpose of counteracting the current; and it is, I think, generally assumed in books and courts of law that all bodies, human and bestial, sink as a rule in water as soon as life is extinct; in other words, it is stated that they remain submerged till decomposition sets in, or sets up such an amount of gas within them as enables them to overcome all resistance from above, and float. If such be the case we must either suppose that the corpses referred to within possessed some special attributes of their own, or that "men are very different in buoyancy" after death than they were during life. Assuredly these men could not have been lost in this way had their bodies been able to float in the one state as well as they were in the other; and I heartily agree with Mr. Hill when he says that "no amount of coolness or presence of mind will either supersede the art of swimming or alter the laws of gravity."

Ashton-under-Lyne W. CURRAN

Resonance of the Mouth-Cavity

THE observation of Mr. John Naylor, forwarded to you by Mr. Sedley Taylor (p. 100), admits of being made with more striking (because louder) results than by the method described, and so far from being a "discovery," is well known to most schoolboys. Tap with the thumb-nail upon the front teeth, and at each tap alter the shape of the mouth-cavity so as to produce the note desired; any tune may then be played loud enough to be heard at the other end of a large room. It is remarkable that without previous practice one instinctively shapes the mouth-cavity so as to produce, in almost every case, the exact note required. GEORGE J. ROMANES

Thunder-Storm at the Cape

A YOUNG man of my acquaintance, who some time ago joined the Cape Mounted Rifles, has just forwarded to me an account of a severe storm which occurred on the evening of Thursday last, April 14. C. TOMLINSON

Highgate, N., June 13

"The storm set in about 6 p.m., whilst the men were at stables, and was accompanied by loud thunder and vivid flashes of lightning. At 6.15 there was a fearful roll of thunder, accompanied by a most vivid flash, which lit up the square for at least thirty seconds. It struck the barracks at the upper end, ran past a room to the stables, which have iron roofs; it ran along the course of the roofs into the stables, striking down two men in the doorway. It then ran along the iron of the manger, flooring all the horses, nineteen in all, and so went to ground. One man was struck in the left shoulder bone, the fluid passing from there under the left arm to his watch in the left-hand trousers pocket, and burnt a hole clean through the silver case. From the watch it struck again six inches below, and travelled round the leg under the knee, and from thence probably to the spurs, as no burn was found below the knee. The extremities of both tracks were marked by large burns, and each track by a burn two inches over. The surgeon says it was the most miraculous escape he ever saw, the watch having saved the man's life. The second man was merely stunned, and lost the use of his legs for some hours; he was standing in the stable behind the first, and although only slightly burnt, is still unable to walk. The other is doing well, but is rather dazed. Ten other men were floored, but soon regained their legs. As to the horses, one was struck dead in the forehead: two others, blind in both eyes, were shot yesterday; and four more blind in one eye are condemned. A horse in town was struck, and his fore-leg broken in four places.

"Within a hundred yards of the barracks is a powder magazine full of powder, fitted with conductors which were struck several times. This occasioned great alarm to the inhabitants, as it contains many tons of powder.

"JOHN P. CUNNINGHAM

"King William's Town, South Africa, April 18"

A Six-Fingered Family

IT may interest some of your readers to hear that there is at present living in Brown's Town, Jamaica, a family in whom the possession of six fingers has been hereditary for at least four generations. Unfortunately they consider the sixth finger a deformity, and always amputate it, so that there is very little opportunity of observing it. There is a little girl there however upon whom this operation has not been performed, and I much regret that, as her parents had taken her up into the hills to work in their provision grounds, I could not see her. As I am informed, the sixth finger springs from the little finger knuckle at right angles to the little finger, and when it is free of it, it turns up parallel to the rest, being a little shorter than the little finger, but quite perfect, with nail and two joints. It is bent and extended with the rest on opening or closing the fist.

Another fact, which I daresay however is usual in such cases,

came under my notice at Brown's Town, viz. two perfectly black parents having a family all pure albinos.

Kingston, Jamaica, May 26 THOMAS CAPPER

Singular Behaviour of a Squirrel

A NEIGHBOUR of mine, whose cottage is thickly surrounded with trees, observed a squirrel, during the severe weather of winter, occasionally stealing food from the troughs set out for the poultry. At first it caused great commotion among the birds, but latterly they were less uneasy in its presence. Taking an interest in the wild creature he began to lay out refuse food for it, including bits of ham, which it greedily appropriated. Getting more courageous, it ventured within doors. After a time it got caught in a trap set for rats underneath the bed. Being freed from its irksome position it was thought that the squirrel would venture no more within doors. Neither the incident of the trap nor confinement for some time within a cage availed to restore to it its original shyness. With the coming of summer its visits have been less regular, but occasionally it looks in still. May not a habit like this, affecting only one out of many, be looked upon as corresponding to a "sport" in the vegetable world, and shed some light on the subject of the domestication of animals? The squirrel seems to have been quite a wild one to start with, for there is no one in the district who had been in the habit of keeping one as a pet. J. SHAW

Dumfriesshire

Hot Ice

IN reply to a very interesting letter on this subject recently published in NATURE (vol. xxiii. p. 504) by Dr. Oliver J. Lodge, I wish to express my views of the theoretical and practical possibility of the experiment of Dr. Carnelley. I wish to start from some well-known principles accepted by everybody acquainted with the mechanical theory of heat and its applications. According to these principles the volume "v" (and also the total amount of internal energy) of water can be expressed as a function of its pressure "p" and temperature "t"; $v = f(p, t)$. The form of this function, which we need not discuss here, will change with the state of aggregation, so that we shall have three different equations expressing the volumes of water in the solid, liquid, and gaseous form.

$v = f_{\mathrm{i}}(p, t)$ ... ... ice
$v = f_{\mathrm{ii}}(p, t)$ ... ... water
$v = f_{\mathrm{iii}}(p, t)$ ... ... vapour
} p and t being considered independent variables.

Geometrically the volumes of ice, water, and vapour will belong to three different surfaces extending between certain limits. Thus the surface $v = f_{\mathrm{i}}(p, t)$, which represents the volumes of ordinary ice, is situated between the limits $q\,p$, $l\,m$, $m\,d$; the surface representing liquid water lies between $m\,n$ and $m\,d$, though it may be extended a little on either side of these limits, if it applies to water heated or cooled over its regular boiling or freezing temperatures, which are situated along the lines $m\,d$ and $m'n$.[1] The values of p and t, which belong to $m\,d$ and $m\,n$, will satisfy two equations—$\phi(p, t) = 0$ and $\psi(p, t) = 0$. At these points the water will change its form of aggregation and pass over in the state of saturated vapour along the line $m\,n$ [equation $\psi(p, t) = 0$], or into ice along $m\,d$ [equation $\phi(p, t) = 0$] in a continuous and *reversible* way. At any other point, which is not situated on $m\,n$ or $m\,d$, water may also be liable to change of aggregation, but this process will not be *reversible*. The line $m\,n$, where the surface $v = f_{\mathrm{ii}}(p, t)$ breaks up and liquid water changes into vapour, is the *curve of tension of saturated vapour* contained in the renowned table of Regnault. The boiling-points of water under varying pressure are situated on $m\,n$, and may be found by solving the equation $\psi(p, t) = 0$. At the point m ($p = 4{\cdot}6$ mm., $t = -0{\cdot}0078$ C.) the line $m\,n$ terminates, but is continued by $l\,m$ [equation $\chi(p, t) = 0$], along which the vaporisation of ice takes place in a reversible way. According to the table of Regnault there is no sudden rupture at the point m, the pressure of saturated vapour at 0° C. being identically the same, if the vapour is in contact with water or with ice. The differential coefficients $\frac{dp}{dt}$ of the functions $\phi(p, t)$, $\psi(p, t)$, and $\chi(p, t)$, or the tangents to the lines $m\,d$, $m\,n$, and $m\,l$ are found by application of Carnot's Theorem to be of the general form $\frac{dp}{dt} = \frac{Ar}{[s - s_1][273 + t]}$ [r = latent heat; s and s_1 = the specific volumes of water in two different forms of aggregation].

The point m, where $m\,n$, $m\,d$, and $m\,l$ unite, is of particular interest. J. Thomson called it "the triple point," and Guldberg the "Fällespunkt" of water. Lately (in *Berichte*, 1880) I ventured to call it the "absolute point of sublimation," not because I wished to introduce a new term for a well-known scientific object, but only to point out some important consequences of the phenomenon just then announced by Carnelley, of which Prof. Lothar Meyer of Tübingen had published an interpretation different from mine. This point m, situated $-0{\cdot}0078$ C. below the ordinary freezing-point of water, is really the upper limit of sublimation, because at any higher temperature ice first changes into water before it evaporates. At $-0{\cdot}0078$ C., where the boiling- and melting-point of water coincide, a real sublimation of ice begins, provided that the barometric pressure does not exceed 4·6 mm. (="the critical pressure" of Carnelley).

Now according to the discovery of Dr. Carnelley, ice at pressures lower than 4·6 mm. would exist by temperatures up to $+178°$ C. Thus the surface $v = f_{\mathrm{i}}(p, t)$, which we have hitherto supposed to be inclosed between the limits $q\,p$, $q\,l$, $l\,m$, $m\,d$ would extend far beyond $l\,m$ nearly up to k, but always at pressures smaller than 4·6 mm. Geometrically this new and unforeseen

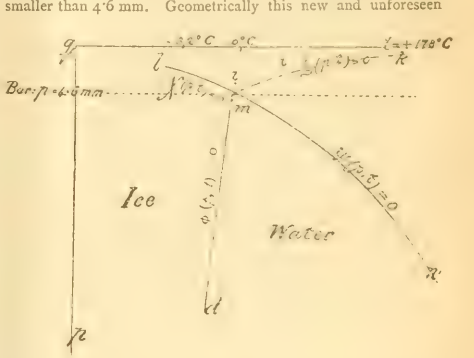

FIG. 1.

extension of the surface of ice is represented by the area $l\,m\,k$. Here the process of Carnelley, whereby ice of low pressure is heated to astoundingly high temperatures, would go on. The area $l\,m\,k$ would of course be entirely a *terra incognita* to the science of the present day, but there is nevertheless no theoretical objection why the surface of ice $v = f_{\mathrm{i}}(p, t)$ should not extend farther than to the limiting line $l\,m$ pointed out by Regnault. Confiding in the experimental proofs already furnished by Dr. Carnelley, I concluded (*Berichte*, 1880): if the surface of ice really extends upwards to about $+178°$ C. there must be a limiting line $m\,k$ to the area $l\,m\,k$, since this area cannot extend so far as to the dotted line in the figure indicating the critical pressure $= 4{\cdot}6$ mm. At this new limit, $m\,k$, corresponding to an equation $\xi(p, t) = 0$, the vaporisation of the "hot ice" may go on in a reversible way, just as liquid water gives up saturated vapour at those pressures and temperatures which belong to the line $m\,n$ (equation $\psi(t, p) = 0$). The line $m\,k$ would in many respects be the continuation of $m\,d$ (just as $m\,l$ forms the continuation of $m\,n$), but naturally the symbols entering the equation of its differential coefficient $\frac{dp}{dt} = \frac{Ar}{(s - s_1)(273 + t)}$ must change their signification on the other side of the point m, so that r here would represent the latent heat of *vaporisation* of the hot ice, s its specific volume, &c. I did not expressly mention this in my paper in the *Berichte*, because I thought it unnecessary. This omission on my side may probably have misled Dr. O. Lodge as to the real meaning of my words, since he declares my opinion that an equation $\xi(p, t) = 0$ having a differential

[1] The surface corresponding to the volumes of aqueous vapour $v = f_{\mathrm{iii}}(p, t)$ is not sketched in the figure, which gives only *the projection* of the surfaces on the plane of co-ordinates p and t, not the real situation of these surfaces in space. The reader will also observe that the limiting lines $m\,n$, $n\,d$, $l\,m$, $m\,k$ are the *intersections* of vertical cylindrical surfaces ("Uebergangsflächen") with the plane t, t.

coefficient $\frac{dp}{dt}$ of the general form above mentioned will still exist for pressures below 4·6 mm. and temperatures higher than +0·0078° C., where it is now supposed to have a *point d'arrêt*, to be "naturally erroneous," an assertion which I hope the learned English inquirer may feel inclined to withdraw after the preceding explanation. Of course the necessity of my conjecture may be disproved by facts—if there really should exist no "hot ice"—but nevertheless it deserves to be discussed as well as the opinion of Dr. Lodge, who considers the existence of hot ice to depend entirely on an irreversible process of vaporisation from the ice resembling the evaporation of water in an atmosphere which is not saturated with damp. This observation only regards the experiment, not the theory. I fully admit that Dr. Carnelley's experiment is carried on in an irreversible way, but that is the case with every distillation or sublimation which is *practically* performed. Nevertheless there exists a line *m n* where the liquid water changes gradually and reversibly into saturated vapour, and that may be the case also with the hot ice at the limit *m k*. Any irregularity in the operation will not exclude the possibility of the existence of an equilibrium established by nature. The difference of temperature between the hot ice in the experiment of Carnelley and the cooled vacuum bottle is no objection to this, because we *might* carry on the operation in quite another way, dispense with the vacuum bottle and the cooling mixture, and keep up the necessary minimum of pressure, which is the only *sine quâ non*, by means of a powerful air-pump. In a similar experiment (with $HgCl_2$) Dr. Carnelley operates in that way. Dr. Lodge, on the contrary, is convinced that ice, which has once passed the triple point *m* can sustain whatever augmentation of pressure and temperature may be applied to it. We may destroy the vacuum, so scrupulously kept up by all experimenters, and allow the air to enter through hot pipes, nevertheless the ice will not melt. I interpret this in the following way:—Dr. Lodge admits that the surface $v = f_1(p, t)$ extends over the limit *l m*, and even surpasses the critical pressure 4·6 mm., the vaporisation of the hot ice going on irreversibly the whole time.[1] This is indeed an interesting hypothesis, which well deserves to be tested by experiments, but yet lacks any foundation from facts. I therefore think that the proper method of resolving the entire problem would be:—

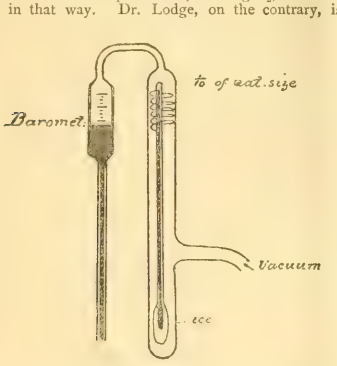

Fig. 2.

1. To try (by experiment) if ordinary ice under low pressure by sufficient supply of heat can be made to pass over the limit *l m* and assume higher temperatures than those corresponding to the equation $\chi(p, t) = 0$ (or Regnault's table).

2. If this should be the case it remains to ascertain if the vaporisation of the "hot ice" tends towards any limit (*m k*), where this process becomes reversible, saturated vapour being formed [my conjecture], or if there is no such limit [theory of Dr. Lodge].

The apparatus employed (see Fig. 2) differs from those recently used by Messrs. Boutlerow, McLeod, L. Meyer, &c., only by its combination with a barometer, by means of which the variation of the pressure of the vapour given up by the ice during the whole process could be exactly measured. The only drawback to this was that the barometer of the apparatus did not *instantly* indicate the variation of the pressure, because the *upper* part of the barometer was made of a very wide glass tube to avoid the influence of capillarity. The effect of the vacuum, which consisted of a 4-litre glass bottle, was very powerful, since the full heat of two strong gas-lamps, each furnished with three pipes, must be employed on the outside of the glass tube in order to raise the temperature of the ice covering the bulb of the thermometer from − 15° C. or − 11° C., up to 0° C. The result of the experiment was (the ice being heated *only by radiation* from the glass tube):—By intense heating the temperature of the ice slowly (in about six minutes) rose from − 11° C. to 0° C., when it became *constant* for half a minute. Then the ice melted, and the first drop of water falling upon the bottom of the heated glass tube was sufficient to crush the apparatus. During the process of heating the niveau of the mercury in the barometer-tube constantly fell, the internal pressure augmenting as the temperature of the ice rose. It was quite impossible to raise the temperature of the ice without simultaneously augmenting the pressure.

Experiment I.		*Experiment II.*
The ordinary barometer showed	= 756·8 mm.	= 771·1 mm.
The barometer of the apparatus showed	= 755·0 mm.	= 769·5 mm.
The initial pressure in the apparatus	= 1·8 mm.	= 1·6 mm.
The initial temperature of the ice	= − 11·0 C.	= − 15° C.
By heating the temp. rose to	= − 8°; the press. = 2·5	t = − 9° p. = 1·8 mm.
,, ,, ,,	= − 6°; ,, = 2·90	t = − 6° p. = 2·6 mm.
,, ,, ,,	= − 4°; ,, = 3·5	The mercury in the stem of the thermometer separated by the heat.
,, ,, ,,	= − 0°; ,, = 4·0	
The ice melted.		

TABLE OF REGNAULT.

Tension of saturated vapour at—	
t = − 20° C.; p = 0·927	
t = − 15° C.; p = 1·700	
t = − 10° C.; p = 2·093	
t = − 5° C.; p = 3·113	
t = 0° C.; p = 4·600	

I also repeated the experiment of Mr. Hannay by substituting a little sealed tube containing frozen water under atmospheric pressure, instead of the bulb of the thermometer. I found, in accordance with Mr. Hannay, that the enveloping ice melted before the ice in the tube.

After the experiments published by Messrs. McLeod, Boutlerow, L. Meyer, v. Hasselt, de la Rivière, and Hannay, I think it may be considered as a matter of fact that ordinary ice under low pressure cannot be heated over 0° C. In the experiments I. and II. I vainly tried to raise the temperature of the ice without simultaneously augmenting the tension of the vapour in the apparatus. It seems probable therefore that the area corresponding to $v = f_1(p, t)$ does not extend farther than to the limit *l m* [equation $\chi(p, t) = 0$], since the temperature of the ice and the tension of its vapour vary almost exactly in the ratio given by Regnault's table, which in Fig. 1 is represented by the line *l m*. We may conduct the heating of the ice so as to follow almost continuously the line *m l* [Experiment I.] without ever being able to pass over it or to reach temperatures situated beyond *l m* (*i.e.* in the area *l m k*). Still I think these experiments to be strictly convincing only in the case of *ordinary ice*. Nobody has yet repeated Dr. Carnelley's experiment exactly in the same way as Dr. Carnelley himself. In his experiment the ice on the bulb of the thermometer is formed not by the freezing of a quantity of water, but by the sublimation and condensation of icy vapour to thin layers. It *may* be possible that ice, by sublimation under low pressure, changes into another allotropic modification, just as the red modification of HgI_2 is changed into yellow iodide by sublimation. In this case we may foresee the existence of a new surface, $v = f_{iv}(p, t)$ on the other side of *l m*. For, according to the principles of the theory of mechanical heat, there ought to be a new function, $v = f_{iv}(p, t)$ for every new allotropic modification of a body which, geometrically, is represented by a surface (?? in the figure). We are scarcely authorised to deny the possibility of the existence of hot ice, since Dr. Carnelley has obtained several pieces of ice, which

[1] *Or:* Dr. Lodge supposes that the volume of ice which has once passed the limits, beyond which liquid water cannot exist, is totally *independent* of the temperature and pressure. In this case no theory can be applied to account for the existence of hot ice, because every theory must start from the assumption that there exists a certain relation between the variables v, p, and t, and that the volume of ice, as long as it *is* ice, is not *arbitrary*, but regulated by an equation $v = f_1(p, t)$. Therefore I do not think that this explanation can be in accord with the views of Dr. Lodge.

did *raise* the temperature of the calorimeter. I have tried to repeat this experiment, but I never could obtain the whole bulb of the thermometer entirely covered with sheets of sublimated ice, and without this the experiment will be illusory. Many times I obtained lozenges of sublimated ice, which did adhere very strongly to the bulb of the thermometer, until it showed + 35° or + 40° C. Then the lozenges generally fell off. I do not consider this to be any deciding proof, as it may depend on a phenomenon similar to that of Leidenfrost, nor do I think it very probable that ice really can exist at those temperatures, but if that should be the case the simplest manner to account theoretically for the existence of hot ice would be to assume a new allotropic modification, since it may be regarded as a matter of fact that *ordinary ice* cannot be heated over the limits pointed out by Regnault. If this should be the case I think that the importance of the discovery of Dr. Carnelley could hardly be overrated.

Upsala, May 28 OTTO PETTERSSON

TEMPERATURE OF RAIN-WATER.—"A Subscriber" asks where he can find records of the temperatures of rain-water when falling, and of the earth a few inches below the surface, during any or all the months of the year.—As regards the British Islands, the most extensive and long-continued observations on the temperature of the soil are those published by the Scottish Meteorological Society since 1857. A *résumé* of the first five years' observations was published in the Society's *Quarterly Report* for October–December, 1862. In the Society's *Journal* (vol. i. p. 320) is a discussion of valuable series of observations made on the temperature of drained and undrained land at various depths; also in *Journal* (vol. ii. p. 273, and vol. iii. p. 211) discussions of hourly observations on the temperature of the soil and of the air at different stations in Scotland. With respect to the temperature of falling rain, little, if anything at all, quite satisfactory, has been accomplished, the practical difficulties in the way being either not apprehended by the observer or not satisfactorily disposed of. Our correspondent may also consult with advantage the publications of the various Continental organisations for the prosecution of forest meteorology.—ED.

NOTES ON ALGÆ[1]

THE publication of the second part of Bornet and Thuret's volume on Algæ seems a fitting opportunity to notice it in some little detail. While the First Part, published in 1876, treated chiefly of the red Algæ, by far the larger portion of this Part treats of the Nostocs; while the First Part contained a good deal of the notes of Thuret, the present is practically the work of Bornet, and the drawings are in almost every instance from this author's pencil.

Under the modest title of Notes, we find in this handsome quarto volume, of over a hundred pages and twenty-four plates, in addition to notes on the higher Algæ, a most exhaustive treatise of a very interesting group of simple Phycochromaceous plants.

The illustrious Thuret had laid the foundation of a knowledge of the Nostocs; his friend Bornet has built thereon a very solid structure. He has not attempted to write a complete monograph of the group, including therein all the "book" species, but having had access to most of the published collections of dried Algæ, to the collections of the Paris and Dublin Herbaria, and to the original types of de Brebisson, Lenormand, Montague, Harvey, Grunow, and Le Jolis, he has performed wonders in the way of clearing up a most tangled synonymy.

It might shock the nerves of some botanists to recommend that all defective descriptions of Algæ—of which no original type specimens exist—ought to be overlooked. We believe, however, that it would be for the advantage of science that such a step should be taken. We may here mention that the collection of Dr. Hassall, from which most of the drawings of that author's "History of British Freshwater Algæ" were made, has been long since dispersed; so far as the Nostocs are concerned, this does not much matter, as all the species were described from authentic specimens still attainable.

The Nostocs (this name is traceable to Paracelsus—"Sic etiam quicquid aër gignit et ex aëre est vivitque vel oritur ut Tereniapin, Nostoch," &c.—and yet no one seems to know its meaning) are well-known plants. One common species makes its appearance on lawn or garden walks in summer or autumn in the form of olive green (rarely bluish), irregular, and more or less shining masses. It is strange to hear the guesses that are made as to the nature of these. We have had them sent to us as the "peculiar spawn of earthworms," and again as the eggs of some foolish frog that had mistaken dry land for water. Some species delight in moist banks over which water continually trickles; some live a wholly aquatic life on stones in streams. The species have an enormously extended, but not yet accurately defined geographical area. As to size, they vary much, some being scarcely visible to the unassisted vision, some forming masses as large as the upper joint of one's thumb.

The details of such a volume as the one before us are too special to be of general interest, so we rest satisfied with indicating the chief contents. The genus Nostoc is treated of very fully; the reproduction of the species by hormogones and by spores is well illustrated. Instead of the term trichome, we would have preferred that of filament, for the former has now obtained such a common usage in another sense among botanists. Despite a wonderful uniformity in their structure, the spores seem to furnish good diagnostic differences. It is unfortunate that they are not as yet known in all the species, while in some they are difficult to hit off. Twenty-nine species are formulated. Carefully-conducted culture experiments, carried on over four years, have proved that Nostoc cells found within the cells of aquatic plants (Potamogeton, &c.) will develop into regular Nostoc colonies, which latter have been traced to the spore-producing stage.

Four species of the genus Nodularia are described and figured. This genus is better known under its more familiar title of Spermosira. *Nodularia litorea* is a somewhat remarkable species. In July, 1874, M. Crié was commissioned to make an inquiry into the cause of a noisome smell proceeding from the little lake of Deauville (Calvados). It would appear that for some years this district had been a regular focus of maladies, and those living near it had remarked that the fœtid odour perceived at times came from a reddish matter which periodically covered the surface of the water. M. Crié soon found that this consisted of ruddy masses of this Nodularian, spreading over the surface of Ruppia, and that its periodic decomposition—at the moment of greatest heat and lowest water—was the cause of the stench. The perfect remedy was found in guiding a stream through the little lake or pond, and thus preventing the too rapid growth of the Alga

Of the other genera treated of we must mention Lyngbya, Plectonema (for *Conferva mirabilis* of Dillwyn), Scytonema (twenty-one species, of which a provisional analysis is given. Some twenty-one species (?) are included under *Scytonema thermale* (Kutz.), and a very important Appendix gives a list of plants determined NOT to belong to the genus, though referred to it); Calothrix (several of our native species are figured and described); and lastly, Glœotrichia (of which six species are admitted).

Enough has been written to prove how valuable an addition to our works on the lower algal forms this volume is. To the worker on this group—ever increasing in interest—this contribution to our knowledge of it will be very welcome. Such will call to mind, too, that there are still lower and more confusing forms of these Algæ, and will be glad to hear that it is probable that the same patient and clever hand hopes shortly to have reduced even them to something like order. E. P. W.

PENNSYLVANIA OIL REGIONS

THREE years ago the Second Geological Survey of Pennsylvania, under the able leadership of Mr. J. P. Lesley, published a report on the oil-well records of the State—a laborious compilation by Mr. J. F. Carll. During the interval the value of this report has been duly tested and acknowledged. It is a treasury of facts classified and indexed for the guidance of the compiler of statistics, the well-sinker, the mining engineer and the geologist, while the general reader may learn much of interest from its pages. Another report by the same author is just about to appear. It forms a volume of about 500 pages with two indexes, twenty-three plates, and an atlas of twenty-two sheets of maps, well-sections, and working drawings of machinery and tools. We have been favoured with advance-sheets of the Letter of Transmission prefixed to the report by Mr. Lesley, from which we make the following extracts:—

"The main feature of the report is the settlement of the true character of the Venango oil-sand group as a distinct and separate deposit, with characteristic marks distinguishing it from the Palæozoic formations of a preceding and a succeeding age; the differentiation of the group into three principal and other subordinate layers of gravelly sand, holding more or less oil or gas; the local variability of these sands, their singular persistency beneath long and narrow belts of country, their change into barren shales elsewhere, and their independence of other oil-bearing sands and shales of an earlier and of a later date."

Some characteristically caustic remarks are made as to the consequences of the contempt entertained by "practical" men for what they consider the "theoretical" opinions of geologists, and a flagrant example is given of the results of trusting to mere empirical guidance. These passages ought to be well studied by oil-men in Pennsylvania and Canada. Mr. Lesley goes on to relate an incident in his own experience. "In 1841," he says, "I was ordered by the chief of the First Geological Survey to report on the counties lying along the New York State line, and down the eastern bank of the Allegheny River, as far as the Kiskiminitas. Other assistants on that survey had already discovered and reported the geological structure of the Allegheny River and Beaver River water basins, and the rate of descent of the rocks southward and south-westward in relation to tide level had been calculated. My business was to follow and locate upon the map the anticlinal and synclinal rolls which locally change and modify this general dip, and to identify the principal coal beds over a large area.

"After the discovery of petroleum (which of course did not in the least set aside or essentially change the structure of Western Pennsylvania as established by the First Survey), I happened to be employed by the Brady's Bend Company to examine their property, and to give them, among other items, an opinion upon the probable existence and depth of oil beneath it. To do this, I merely did what any geologist who had thoroughly studied that country would have done; I calculated the vertical distance from the oil sand on Oil Creek up to coal A, then I calculated the dip of the measures between Oil Creek and Brady's Bend, and then I identified coal A at Brady's Bend. I reported that the Venango oil sand, *if it extended under ground as far as Brady's Bend*, ought to lie at 1100 feet beneath water-level. Any geologist who knew the country could have done this. It required no genius, no uncommon knowledge, nothing but a plain, simple, systematic, or scientific, in other words, true theoretical method of applying known facts for discovering the unknown. Any oil-man could have done the same if he had noticed the rocky layers as he went up and down the river, and put this and that carefully together.

"Yet, when after a few months, oil was actually struck at Brady's Bend within a few feet of the depth which I had assigned to it, the astonishment of all classes of oil-men was ludicrously extravagant; a score or two of copies were made from the manuscript report, and these copies passed from hand to hand as precious things, and their author was looked upon as a prodigy of mental penetration, and was offered large sums of money to locate wells in different districts, none of which offers, of course, were accepted, because he was as ignorant of the *actual existence of an oil-bearing sand in any given locality* as everybody else.

"The story has its moral. Let 'practical' men believe in and respect the slowly, carefully reached conclusions of 'theoretical' men enough to take them into consideration, so far as to comprehend them, and to govern themselves by them in their own collection and collation of facts relating to their own pecuniary interests."

Notwithstanding the amount of detailed information now collected regarding the occurrence of the liquid hydrocarbons in these ancient American formations, it must be frankly confessed that we seem to be as far as ever from a clue to their source and history. "The origin of petroleum," says Mr. Lesley, "is still an unsolved problem, and Chapter 26 of this Report merely suggests queries respecting it. That it is in some way connected with Palæozoic sea-weeds, the marks of which are so infinitely abundant in the rocks, and with the infinitude of coralloid sea-animals, the skeletons of which make up a large part of the limestone formations which lie several thousand feet beneath the Venango oil-sand group, scarcely admits of dispute; but the exact process of its manufacture, of its transfer, and of its storage in the gravel beds, is utterly unknown. That it ascended rather than descended into them seems indicated by the fact that the lowest sand holds oil when those above do not, and that upper sands hold oil where they extend beyond or overhang the lower. The chemical theory, so-called, which looks upon petroleum as condensed from gas, the gas having been previously distilled from the great black shale formations (Marcellus and Genessee), must face the objection that such a process, if chemically possible, which is doubtful, ought to have distributed the oil everywhere, and permanently blackened and turned into bituminous shales the entire thickness of this part of the earth crust, several thousand feet thick. It fails to explain the petroleum obtainable from the Cannel coals, and from the roof shales of bituminous coal beds. And it fails also to explain the entire absence of petroleum from immense areas of not only shales, but sand and gravel rocks equally underlaid by the Marcellus and Genessee formations."

One of the most generally interesting questions in the report is one discussed in great detail by Mr. Carll—an episode in the history of the glacial period in North America. Certain oil-bearing river-gravels are connected with a very thick "deposit of Canadian rock fragments not only upon the surface, but to the depth of several hundred feet beneath it in Northern Pennsylvania, a deposit which forms a great belt, more than a thousand miles long, across the continent from Cape Cod in Massachusetts to Iowa and Minnesota beyond the Mississippi River. It was brought from the north by a vast sheet of moving ice which filled the great lakes and rode over the highest mountains to the south of them—burying all New England and New York, Northern New Jersey, Northern Pennsylvania, the Western Reserve in Ohio, and large portions of the States lying further west—projecting long tongues or slowly moving torrents of solid ice southward as far as and even beyond the Ohio River in Kentucky. It drove slowly before it the reindeer, musk ox, caribou, moose, and other Arctic animals whose bones are found in the diluvial clays of the Kentucky caves; while the walrus inhabited the shores

of the Atlantic as far south as the Ashley River in South Carolina. The Esquimaux race no doubt accompanied these animals into the Gulf States, just as it did in France as far south as the Pyrenees. By the deposit of this vast pile of moraine matter, sand, clay, scratched rocks and huge boulders, the valleys by which our rivers had previously flowed into Lake Erie were filled up so that the waters were turned southward into the Ohio."

"THOUGHT-READING"

THE public mind has of late been somewhat agitated by the doings of a Mr. Bishop, who has come before the world of London society in a capacity no less startling than that of a professed reader of thought. Armed with a favourable letter of introduction from Dr. W. B. Carpenter, he has not only taken by storm the general public and daily press, but also succeeded in convening an assembly of scientific men to witness his performance, which in point of numbers and importance resembled in miniature a *soirée* of the Royal Society, while still more recently he has had the honour of exhibiting his powers before the Heir Apparent to the Crown. There is no doubt that Mr. Bishop owes this wide and sudden celebrity to the patronage which was extended to him by the great opponent of all humbug; and although Dr. Carpenter doubtless intended his letter to exert a salutary influence by recommending Mr. Bishop to the attention of the credulous, it is to be regretted that it served to recommend him also to the attention of the scientific. This is to be regretted, because the result was to endow the powers which were afterwards exhibited with a fictitious degree of importance in the eyes of the public, and also to bring a large number of distinguished men into the somewhat undignified position of acting the stalking-horse to Mr. Bishop's notoriety. But however this may be, it seemed to Prof. Croom Robertson worth while to make a more careful trial of Mr. Bishop's powers than was possible in the first crowded assembly, and he therefore invited Mr. Francis Galton, Prof. E. R. Lankester, and myself, who were all present on the first occasion, to join him in an investigation. When we had assented to the proposal, Mr. Bishop was invited to meet us at Prof. Croom Robertson's house. He immediately accepted the invitation, and it is but just to state that throughout the investigation which followed he placed himself entirely in our hands, and with the utmost good nature submitted to all our requirements. He professes that he is himself ignorant of his *modus operandi*, and merely desires that this should be adequately investigated and satisfactorily explained.

Two meetings were arranged. At the first, which was held on May 28, Prof. Lankester was not able to attend, and his place was taken by Mr. Leslie Stephen. Mr. Alfred Sidgwick was also present. At the second meeting, held on June 11, there were present as before, Prof. Croom Robertson, Mr. F. Galton, and myself, but Mr. Leslie Stephen and Mr. Alfred Sidgwick were absent, while Prof. Lankester was present. The room in which both meetings were held was a double drawing-room of the ordinary shape of those which usually have folding-doors; here however the folding-doors were absent. The extreme length of the room was 36 feet, the width of its front part was 19 feet, and of its back part 12 feet.

First, Mr. Bishop was taken out of the room by me to the hall down stairs, where I blindfolded him with a handkerchief; and, in order to do so securely, I thrust pieces of cotton-wool beneath the handkerchief below the eyes. In all the subsequent experiments Mr. Bishop was blindfolded, and in the same manner. While I was doing this, Mr. Sidgwick was hiding a small object beneath one of the several rugs in the drawing-room; it having been previously arranged that he was to choose any object he liked for this purpose, and to conceal it in any part of the drawing-room which his fancy might select. When he had done this the drawing-room door was opened and the word "Ready" called. I then led Mr. Bishop up stairs, and handed him over to Mr. Sidgwick, who at that moment was standing in the middle line between the two drawing-rooms, with his back to the rug in question, and at a distance from it of about 15 feet. Mr. Bishop then took the left hand of Mr. Sidgwick, placed it on his (Mr. Bishop's) forehead, and requested him to think continuously of the place where the object was concealed. After standing motionless for about ten seconds Mr. Bishop suddenly faced round, walked briskly with Mr. Sidgwick in a direct line to the rug, stooped down, raised the corner of the rug, and picked up the object. In doing all this there was not the slightest hesitation, so that to all appearance it seemed as if Mr. Bishop knew as well as Mr. Sidgwick the precise spot where the object was lying.

This is Mr. Bishop's favourite experiment; so I may give some of our other observations relating to it before passing on to the variations which we introduced. It was soon found that he succeeded much better with some of us than with others; so at the second meeting, in order to make a numerical comparison, he was requested to try two experiments with each of the four persons who were present. With Mr. Galton, Prof. Robertson, and Prof. Lankester he failed utterly, while with myself he succeeded once perfectly and the second time approximately. For on the first occasion I concealed a pocket-matchbox upon the top of a book behind the leather lap of a book-shelf. After feeling along the rows of books for some time he drew out the one on which the matchbox was lying. In the second experiment I placed a visiting-card on the key-board of a grand piano and closed the cover. After going about the room in various directions for a considerable time he eventually localised the piano, and brought his finger to rest upon its upper surface about six inches from the place where the card was lying. It will thus be seen that his success with me, although so much better than with any of the other three persons present that evening, was not so immediate and precise as it had been with Mr. Sidgwick the evening before. It has also to be mentioned that in one of the experiments which he tried with Prof. Robertson the evening before, he was, after a good deal of feeling about, successful in localising a particular spot on an ordinary chair which Prof. Robertson had selected as the spot to be found. From this it will be seen that it made no difference whether a particular article or a particular spot was thought of; for if the subject thought of was a certain square inch of surface upon any table, chair, or other object in the room, Mr. Bishop, in his successful experiments, would place his finger upon that spot. Neither did it make any difference whether the article or place thought of was at a high or a low elevation. Thus, for instance, in one of the experiments I placed a small pencil-case high up in the chandelier of one of the drawing-rooms. There was first a great deal of walking about in various directions, examining tables, book-shelves, &c., so that it was thought that the experiment was about to prove a failure. (It may here be mentioned parenthetically that in all the experiments tracings were taken of the routes which Mr. Bishop traversed, but it seems needless to occupy space with recording the analysis of these results.) Then, while feeling over the surface of a table in the other drawing-room, and not far from the corresponding chandelier, Mr. Bishop suddenly pointed at arm's length vertically to the ceiling. He remained motionless in this position for a few seconds, and then set off at a brisk pace in a straight line to the other drawing-room, until he came beneath the other chandelier. As his finger was all this time pointing to the ceiling, it

touched this chandelier on his coming beneath it. He then stopped and pointed as high as he could, but not being a tall man, was not able to touch the pencil-case, which had been purposely placed above his reach. After satisfying ourselves that his determination to reach up at that particular spot could not be attributed to accident, but rather that his finger appeared to be smelling the object of his search, the experiment was concluded. As a rule, unless success is achieved within the first two or three minutes, it is never achieved at all; but in some cases, as in the one just quoted, after several minutes of feeling about in various places and directions, a new point of departure seems suddenly to be taken, and Mr. Bishop starts off straight to the right spot. As an instance of this I may quote another experiment, in which I placed a shilling beneath a sheet of paper lying on a table which was crowded with other articles. After going about the room in various directions for a considerable time, this table was reached, apparently by accident, and just at the time when I was thinking that the experiment would certainly prove a failure, Mr. Bishop suddenly became more animated in his movements, and exclaiming "Now I am within two feet of it," began to hover the point of his finger over the table, and eventually brought it down upon the sheet of paper just where the shilling was lying beneath.

Mr. Bishop can also very frequently localise any spot on his subject's person of which the subject may choose to think. As in all other cases he presses the hand of the subject upon his forehead with one hand, and uses the other as a feeler. Here again he succeeds much better with some persons than with others, and the persons with whom he succeeds best are the same as those with whom he does so in his other experiments. Thus he altogether failed with Mr. Galton, although the latter, in order to fasten his attention the more exclusively on one particular spot, pricked this spot with a needle. With Prof. Lankester success was partial; for while he thought of the point of his nose, Mr. Bishop was only able to say that the point thought of seemed to occupy the median line of the body on the front aspect. But on a previous occasion at Bedford Square Mr. Bishop localised correctly a pain (slight toothache) from which Prof. Lankester was suffering. With Prof. Croom Robertson success was better, though not quite perfect, for while the place thought of was the ball of the right thumb, Mr. Bishop localised it in the right wrist. In the only two experiments tried in this connection with myself the results were somewhat peculiar. In the first experiment I thought of a spot situated under the left scapula, and Mr. Bishop localised it as situated under the right; in the second experiment I thought of my right great toe-nail, and for a long time Mr. Bishop prodded round and on the left great toe-nail, though he eventually changed to the right one, and so localised the spot correctly. In both these experiments, therefore, it seemed that with me Mr. Bishop experienced a strong tendency to confuse symmetrically homologous parts.

From this brief summary of the results gained by following Mr. Bishop's own methods, it will be seen that on the whole his power of localising objects or places thought of by a person whose hand he clasps is unquestionably very striking. Of course the hypothesis which immediately suggests itself to explain the *modus operandi* is that Mr. Bishop is guided by the indications unconsciously given through the muscles of his subject—differential pressure playing the part of the words "hot" and "cold" in the childish game which these words signify. Mr. Bishop is not himself averse to this hypothesis, but insists that if it is the true one he does not act upon it consciously. He describes his own feelings as those of a dreamy abstraction or "reverie," and his finding a concealed object, &c., as due to an "impression borne in" upon him. But however this may be (and of course we had no means of testing the statement) all our experiments have gone to show that the hypothesis in question is the true one, and that Mr. Bishop owes his success entirely to a process of interpreting, whether consciously or unconsciously, the indications involuntarily and unwittingly supplied to him by the muscles of his subjects. Thus when his subject is blindfold and loses his bearings, failure results. Failure also results if the connection between Mr. Bishop and his subject is not of a rigid nature—a loose strap, for instance, being apparently of no such use to him for the establishment of connection as a walking-stick. Similarly, although he was very successful when he grasped my left hand when I did not know where the object was concealed, but when my left wrist was held by Mr. Sidgwick, who had concealed the object; he failed when, under otherwise similar circumstances, Mr. Sidgwick held my right hand—so establishing a limp instead of a firm connection through my person.

Lastly, a number of other experiments were tried, in deference to some statements which Mr. Bishop made concerning his occasional success in reading thoughts of a kind which could not be indicated by muscular contraction. From these experiments, it is needless to say, we did not anticipate any results; but (with the exception of Prof. Lankester) we thought it was worth while to make them, not only because Mr. Bishop seemed to desire it, but also to satisfy the general public that we had given the hypothesis of "thought-reading," as well as that of "muscle-reading," a fair trial. The experiments consisted in the subject looking at some letter of the alphabet which Mr. Bishop could not see, and the latter endeavouring to read in the thoughts of the former what the letter was. Although this experiment succeeded the first time it was tried, it afterwards failed so frequently that we entertain no doubt as to the one success having been due to accident, and therefore conclude that if Mr. Bishop has any powers of "thought-reading" properly so-called, he has failed to show us evidence of the fact.

Deeming it a remarkable thing that such precise information as to a mental picture of locality should be communicated so instantaneously by unconscious muscular movement, we thought it desirable to ascertain whether Mr. Bishop, who is able so well to interpret these indications, is endowed with any unusual degree of tactile sensibility or power of distinguishing between small variations of resistance and pressure. We therefore tried the sensitiveness of his finger-tips with the ordinary test of compass-points, but found that he did not display more than a usual delicacy of tactile perception, while his power of distinguishing between slight differences in weights placed successively on a letter-balance concealed from his eyes was conspicuously less than that displayed by Prof. Croom Robertson. As Mr. Bishop is not opposed to the hypothesis by which we conclude that his results are obtained, there is no reason to suppose that he tried to depreciate his powers of tactile sensibility and of distinguishing between small differences of weight. In their main features Mr. Bishop's experiments are frequently performed as an ordinary drawing-room amusement, and we are therefore inclined to think that he does not enjoy any peculiar advantages over other persons in regard to sensitiveness of touch or power of appreciating pressure, but that his superior success in performing the experiments is to be ascribed merely to his having paid greater attention to the subject.

In conclusion, we desire to express our thanks to Mr. Bishop for the trouble which he has taken in submitting to the numerous experiments, the general results of which have now been stated.

This report has been read in proof by Prof. Croom Robertson, Mr. Francis Galton, and Prof. E. R. Lankester, and meets with their full approval.

GEORGE J. ROMANES

THE WEATHER AND HEALTH OF LONDON[1]

II.

AN examination of the curve for the whole mortality (Fig. 4, NATURE, vol. xxii. p. 144) shows that the great preponderance of deaths in London takes place during the coldest months of the year. Of the diseases to which this excessive mortality is due, the first place must be assigned to diseases of the respiratory organs, the more marked of which are given in Figs. 12 to 15. About one in eight of all deaths that occur is caused by bronchitis, and one in sixteen by pneumonia; so that nearly one-fifth of the deaths is occasioned by these two diseases of the respiratory organs. Our researches appear to warrant the conclusion that the greatest fatality from these diseases occurs when the temperature is between 32° and 40°. In New York, when the winter temperature is 10°·0 lower than in London, the mortality from bronchitis and pneumonia is greatly less; on the other hand, in Melbourne, where the winter temperature is about 10°·0 higher than that of London, the mortality from diseases of the respiratory organs forms but a small fraction of the whole deaths.

These four curves of the mortality from diseases of the respiratory organs are substantially the same, each having its maximum in the cold months and its minimum in the warm months. Asthma shows, in the amplitude of its annual range, the greatest sensitiveness to weather, and pneumonia the least. They all show, though in different degrees, a double-ridged maximum: the one ridge being in the middle of January, when the temperature falls to the annual minimum, and the other in March, when the combined qualities of cold and dryness are at the annual maximum. Asthma and bronchitis are decidedly at the maximum when the weather is coldest, whereas laryngitis has its maximum in March, when the weather is coldest and driest, the last disease thus forming the link connecting the more strictly throat diseases with diseases of the nervous system.

But an element of weather other than mere temperature plays an important part in bringing about the high death-rate from these diseases. That deleterious atmospheric influence is fog; and in cases where the fog is dense and persistent the mortality from diseases of the respiratory organs becomes truly appalling, as happened in London early in 1880, when the mortality was nearly doubled. An examination of the fogs of London shows that they do not commence till the autumnal equinox; and it is at this epoch that asthma (Fig. 12), by far the most sensitive of all diseases to fog, starts from its annual minimum; and in the end of November and begin-

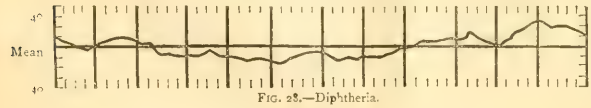

Fig. 28.—Diphtheria.

ning of December, when fogs become most frequent, the curves for asthma and bronchitis shoot up with startling suddenness.

Figs. 16, 17, and 18 represent the curves for three of the nervous diseases, viz. apoplexy, convulsions, and cephalitis. Apoplexy will be observed to show a double-ridged maximum quite analogous to that of the diseases of the respiratory organs; whereas, in the case of convulsions, the maximum may be regarded as quite single, and occurring in spring, this being the season when nervous diseases generally are most fatal. On the other hand, the curve for cephalitis stands alone among nervous diseases as having its annual maximum somewhat later, and keeping above the mean till at least the end of July, thus covering that portion of the year when the climate is driest and hottest, as well as driest and coldest. The intimate relations observed between the curve for suicides (Fig. 19) and that for cephalitis is very striking.

The maximum mortality for whooping-cough, Fig. 20, gout, Fig. 21, and phthisis, Fig. 22, occur in the same season as that for the nervous diseases. The maximum mortality from whooping-cough occurs in the spring months, and the curve suggests that this is more a disease of the nervous system than of the respiratory organs, a view which, singularly enough, was maintained by the elder Dr. Begbie, one of the most distinguished of our Edinburgh physicians, upwards of thirty years ago. The relations of gout to diseases of the nervous system are too obvious to call for remark. Phthisis is one of the two most fatal scourges of our British climate, one out of every eight deaths which occur being caused by consumption. Its mortality-curve, Fig. 22, shows unmistakably its intimate relations to nervous diseases, thus affixing greater significance to its known complications with hereditary insanity, scrofula, and some other mental diseases.

Reference has been made to the influence of the heat of summer on certain of the nervous diseases. That influence acts fatally, both indirectly through the bowels in the case of the young, and directly on the nervous centres. The curve for convulsions, Fig. 17, is identical with that for teething, Fig. 23, and it may be added that the curve for hydrocephalus is simply a reproduction of the same curves. Now these curves show a small, but distinct, and, as revealed by each year's figures, a constantly recurring secondary maximum in summer, which in the case of London is almost wholly due to the bowel complications of these diseases. The curve (Fig. 24) for convulsions for New York, where the summer temperature is 10°·0 hotter than in London, shows this feature of the curve enormously magnified, so much so, indeed, that instead of being, as in London, an insignificant secondary maximum, it stands out as the prominent feature of

the curve. Whilst this result is doubtless largely due to complications with bowel complaints, it is, as an examination of the statistics shows, in no small degree caused by the direct influence of the great summer heat of New York on the nervous centres. This is impressively shown by the mortality curve for the whole of the nervous diseases (Fig. 25), which is even more pronounced in this particular than the curve for convulsions alone (Fig. 24). Keeping this fact in view, the peaks showing an increased fatality in London from cephalitis (Fig. 18) and suicides (Fig. 19) during July and August acquire, in the eyes of the physician, a more impressive significance.

The curve for the whole mortality (Fig. 4, NATURE, vol. xxiv. p. 144) shows September and October to be two of the healthiest months of the year. The three curves, scarlet fever (Fig. 26), typhoid (Fig. 27), and diphtheria (Fig. 28), are the most striking exceptions to this, these curves all indicating either a large increase in the death-rate or a high mortality during these months. While closely related to each other, each of these three diseases has a distinct individuality of its own as regards the times of occurrence of the annual maxima and minima, and the varying amplitudes of their range from the mean line. It is a singular circumstance that diphtheria shows closer relations in its death-rate with typhoid than with scarlet fever.

Several other diseases suggest close alliances with each other through their seasonal death rates. Thus the curve for mortification is substantially that of nervous diseases, and the curves for erysipelas and puerperal fever are in all essential respects the same, a fact of singular suggestiveness to the family practitioner. The curve for old age is exactly parallel to that of paralysis, the old man's disease. The curves for skin diseases, rheumatism, dropsy, pericarditis, Bright's disease, and kidney disease exhibit most striking, and in many cases the closest alliances with each other. Lastly, while bowel complaints attain their greatest mortality when the temperature is highest, diseases of the respiratory organs when it is lowest, nervous diseases during the dry weather of spring and early summer, and

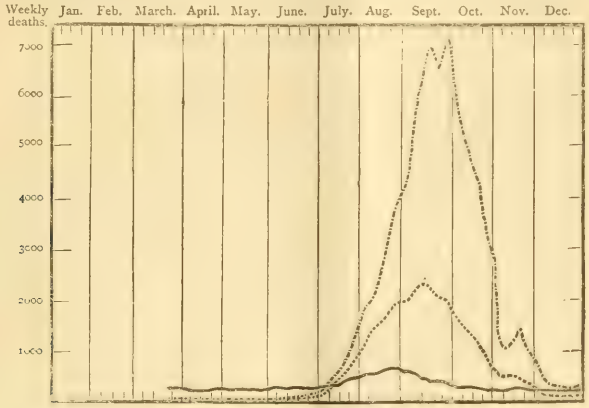

FIG. 29.—The Great Plague of London.

skin diseases and certain fevers during the raw weather of autumn and early winter, such diseases as ileus, that are quite removed from weather influences, exhibit curves which show no obedience whatever to season, but only a succession of sharp, irregular serratures resembling the teeth of a saw.

Atrophy and debility are most fatal to the very young in summer, but to the aged in winter; in the former case the complication being with bowel complaints, and in the latter with diseases of the respiratory organs. The annals of influenza show that a special character is given to this epidemic according to the season of the year in which it occurs. Thus when it occurs in spring the head and nervous system are most affected, but the bowels when the epidemic prevails in summer and autumn.

Fig. 29 shows by the doubly-dotted line, or highest curve, the weekly mortality of London during the Great Plague of 1665, the lower dotted curve the mean weekly mortality of the last six plagues, and the solid curve the mean weekly mortality from all other diseases during the continuance of the last six plagues. The manner in which the plague, as a death-producer, obeyed the weather is striking, and full of interest. It did so exactly in the way in which we have seen bowel complaints to be influenced by weather. The curve of mortality for the plague bears no resemblance whatever to that for typhus, or indeed any other disease except bowel complaints. The fact that the progress of deaths from plague in relation to weather resembles so closely the corresponding progress of deaths from bowel complaints raises the question whether there may not be a closer alliance between them than has been suspected. If we are correct in regarding such a question as a fair outcome of this investigation of the relations of weather and health, it results that such investigations may occasionally point to a seat of morbid processes which have been cloaked by prominent phenomena, apparently of a primary, but in reality of a secondary character.

ALEXANDER BUCHAN

NOTES

THE death of Sir Josiah Mason on the 16th inst., at the advanced age of eighty-six, closes a remarkable career. Born at Kidderminster in humble circumstances, he began life as a street hawker of cakes, and after trial of shoemaking, baking, and a variety of other things in his native place, he went to Birmingham and found employment in the gilt toy trade. In 1824 he set up on his own account as a manufacturer of split-rings by machinery, and he afterwards added the manufacture of stee pens, of which he became really the largest producer, though less known than Gillott and Mitchell, owing to his pens being supplied by Messrs. Perry of London. He shares the credit o perfecting the modern steel pen, the history of which practically

dates from the discovery of the art of splitting by machinery. Sir Josiah Mason also carried on for many years the business of electro-plating, copper-smelting, and india-rubber making, along with the late George Richard Elkington. While he was very much a self-taught man, his very liberal benefactions indicated his sense of the value of good education. Conspicuous among these is the Erdington Orphanage, established at a total outlay of 300,000*l.*; and the munificent gift to Birmingham of a Science College (the building of which cost 60,000*l.*, while the total value of the endowment is probably little short of a quarter of a million) is fresh in public memory.

OUR readers will learn with profound sorrow the loss which biological science has sustained in the death, at the comparatively early age of fifty-one, of one of its most brilliant and gifted cultivators, Prof. Rolleston of Oxford. He had spent the greater part of the winter in Southern Europe, his medical advisers having hoped that a warmer climate and rest from his incessant labours might have averted the malady with which he was threatened. All precautions however proved unavailing. He returned to England about a fortnight ago in a sinking state, and died at his home on Thursday, the 16th inst. We propose to give a sketch of Dr. Rolleston's scientific career in our next number. Immediately after the funeral a meeting of Prof. Rolleston's old pupils was held in the Museum, with the object of perpetuating his name by some suitable memorial. A committee was formed, with power to add to its number; the following gentlemen being elected honorary secretaries:—Dr. C. Mansell-Moullin, 17, George Street, Hanover Square, W., and Dr. Theodore Acland, St. Thomas's Hospital, S.E., London; Mr. E. B. Poulton, M.A., Wykeham House; and Mr. A. P. Thomas, M.A., Anatomical Department Museum, Oxford.

THE Council of Owens College, at their meeting on Friday, June 17, elected Dr. Arthur Schuster, F.R.S., to the Professorship of Applied Mathematics in Owens College. Dr. Schuster was a distinguished student of Owens College in 1870–71; he then proceeded to Germany, studying mathematics and physics under Kirchhoff, Weber, and Helmholtz. On his return he first occupied the position of Demonstrator in Physics at Owens College, lecturing on the Mathematical Theory of Electricity. Afterwards he continued his studies at Cambridge under Maxwell and Rayleigh, publishing several papers on the higher branches of physics. In 1874-75 he was intrusted with the conduct of the Government expedition to observe the total eclipse in Siam, the results of his observations being printed in the *Philosophical Transactions* for 1878. In 1878 he undertook a similar expedition to Colorado, and in the following year he was elected a Fellow of the Royal Society.

THE Davis series of lectures upon zoological subjects will be given in the lecture-room in the Society's Gardens, in the Regent's Park, on Thursdays at 5 p.m., commencing June 16, as follows:—June 16—Whales, by Prof. Flower, LL.D., F.R.S.; June 23—Dolphins, by Prof. Flower, LL.D., F.R.S.; June 30—Extinct British Quadrupeds, by J. E. Harting; July 7—The Limbs of Birds, Prof. W. K. Parker, F.R.S.; July 14—Birds, Ancient and Modern, by W. A. Forbes; July 21—Zoological Gardens, by P. L. Sclater, F.R.S.; July 28—Chameleons, by Prof. Mivart, F.R.S. These lectures will be free to Fellows of the Society and their friends, and to other visitors to the Gardens.

AMONG other features of the forthcoming meeting at York, the noble Guildhall is placed at the Association's use as reception room. The theatre of the Museum of the Yorkshire Philosophical Society has been granted for the Geological Section. The beautiful grounds, containing the ruins of St. Mary's Abbey, &c., will be open to members and associates. The Yorkshire Fine Arts Institution will also be open, and the great hall will be used for some of the evening meetings. The Minster will be thrown open for inspection. Excursions are being organised to several places of interest, including Scarborough (where the Spa Company give free admissions), Whitby, Castle Howard, and the works of Messrs. Bolckow, Vaughan, and Co., at Middlesborough.

THERE has been recently some talk of establishing at Athens or Smyrna an American Institute for the training of Archæologists, and as a permanent committee for archæological research and correspondence. Two institutes with like aims are at present in existence, viz. the German Institut für archäologische Correspondenz, having its seat in Rome, with a branch in Athens, and the École Française d'Athènes, which has a branch in Rome. Mr. Thomas Davidson describes the work of these in a recent issue of the *Nation*, and advocates Smyrna as the place for the American Institute, as offering a more promising field of research than Athens, while there would be a better prospect of getting any antiquities discovered for museums. The cost of such an institution is estimated at 5000 dollars to begin with, for a library and necessary apparatus, and about 6000 dollars a year afterwards.

THE fourth and fifth numbers of *Naturen* for 1881 contain interesting summaries, by Dr. Hercules Tornö, of the results obtained by him, during the Norwegian Arctic Expedition, of the depths of the Arctic seas; the amount of salt contained in the water at various depths and at different distances from land; and the variations observable in the relative quantities of the different constituents of the air contained in sea-water. In regard to the latter point, it may be observed that the mean amount of oxygen present in the air was found to diminish with increasing depth below the surface of the water from 35·3 at the surface, to 32·8 between 1000 and 1400 fathoms; while the relative quantity of the nitrogen present rose with the increased depth from 13·1 at the surface to 14 between 600 and 1000 fathoms. Carbonic acid was found both in a gaseous and basic form.

WE notice a very interesting lecture which has been given at St. Petersburg on the use of the heliograph during the Trans-Caspian war. The heliograph used in the Russian army is that of Mans, and the alphabet is the usual one, that of Morse. The smaller system, which is employed in cavalry, transmits signals to a distance of seventeen miles, and the larger, employed in forts, has a double power. All independent parts of the army, on their march to Akhal-Tepe, had their "heliograph-drafts," and owing to the bright sky of the steppe, and to the level country, the heliograph was continuously used for establishing communication between different parts and small detachments of the army. The heliograph was at work during all the battles, and experiments were made as to the use of it during night, by means of lunar light, as well as with special lamps. The latter, however, being fed with turpentine, which evaporates very soon during the hot days of the summer, did not render great service. It was observed also that the sight of those who receive the heliogram gets very soon fatigued, which occasions error. But altogether the heliograph has rendered very great services during this campaign.

THE French Minister of Postal Telegraphy recently sent to the several telegraphic offices forms for recording all the observations connected with thunderstorms. The forms have been drawn up by M. Mascart, the head of the Meteorological Office, and printed at its expense.

A REPORT has been presented to the Paris Municipal Council on the state of telephonic exchanges in Paris, and the propriety of putting a tax on them for the use of sewers in which the wires are located. The number of telephonic halls will be increased, and six of them will be established shortly, which will bring

their number to ten. At present the number of persons renting wires is a little more than 1000, and the average number of messages a little more than five a day for each.

M. Marey has asked the Paris Municipal Council for the grant of a space of 1200 metres in the Park of the Champ de Mars for establishing a zoological station; but such a large space could not be afforded without inconvenience to foot-passengers, so he has accepted the grant of a space which was tendered to him at Passy, in the Park of Princes.

The Congrès archéologique of France holds its forty-eighth session at Vannes (Morbihan) on June 28. Among other subjects to be discussed are the megalithic monuments of the Gulf of Morbihan, the chronology of sepultures, influence of soil on the distribution of megalithic monuments, bronze objects and other remains found in tombs of Brittany, Gallic and Roman coins, ante-Roman remains in Brittany.

Twenty shocks of earthquake were reported from Szt. Ivan Zelina and Blazedotoc (Hungary) between May 20 and June 7. Some rather severe shocks also occurred on June 11 and 12, direction north-east to south-west.

The Caucasian Museum at Tiflis is fast approaching completion under the active and energetic direction of Dr. Radde. The visitors from Western Europe, who are expected at the Archæological Congress, will already find a tolerably numerous collection of natural history objects and archæological specimens.

The discoveries of remains of palæolithic man in Russia continue to be most interesting. Recently M. Shaposhnikoff discovered a great quantity of stone implements in the district of Valdaï, where a forest has been cut down and the wind has denudated the sand of the subsoil. The implements belong to four categories: (1) knives and saws similar to those of Moustier, St. Acheul, and Solutre, more perfect than any found previously; (2) the same in miniature, most accurate, and made of the finest kind of flint; they might have been used as ornaments, or for tattooing; (3) figures of animals and men made in flint, and relief pictures of the same, also in flint; (4) ornamental designs on stone. The collection is very rich, especially in miniature implements.

A little book just published by the Kössling'sche Buchhandlung (Gustav Wolf) of Leipzig is named "Naturwissenschaftlich-mathematisches Vademecum," being an alphabetical and systematic compilation of all modern publications in the domains of natural sciences and mathematics.

At the meeting of the South-Eastern Railway Company the other day Sir Edward Watkin announced the complete success of the preliminary borings of the Channel Tunnel, and the resolution of his own Company on this side and the French Company on the other to make a further important step. A gallery seven feet in diameter has already been driven from the shaft near Abbots' Cliff for half a mile towards France, and an agreement has been made to push forward a similar headway under the sea for a mile on each side of the Channel. At the present rate of progress this will probably be done within the next six months, and then it is expected that the further nine miles on each side will be undertaken at once. All the conditions seem favourable to the project. The soil is found to be exactly similar at both ends. It is, as was expected, grey chalk impervious to water; and there is every reason to anticipate that it will be found to stretch in an unbroken bed across the Channel. Last week the machinery excavated sixty-seven yards of lineal distance, equal to about two miles a year. At this rate the two headways might meet under the middle of the Channel in about five years; and probably a nearly equal period might be occupied in enlarging this mere seven-feet burrow to a capacious railway tunnel.

It is proposed in Edinburgh to make a three months' trial of lighting Princes Street and the North Bridge as far as the Tron Church with the electric light, on the Brush system.

Birmingham has resolved to invite the British Association to hold their annual meeting for 1883 in that town.

The last number of the *Journal de Physique* describes a set of registering electrometers and magnetometers which are being tried at the Collège de France. The magnetic bars and the apparatus generally are very small. The instruments have been invented by M. Mascart, who believes they will give trustworthy results, and will compare favourably with the large magnetometers used in Kew and other places.

The past winter cold in Norway, between October, 1880, and March, 1881, has exceeded the normal mean by 7° C. The greatest cold yet registered at any of the Norwegian meteorological stations occurred between January 13 and 15. At Karasjok, the lowest temperature was observed on February 4, when the thermometer fell to −50°·6 C., the lowest ever noted in Norway with trustworthy instruments.

A work on the Butterflies of Europe, illustrated and described by Dr. Henry Charles Lang, F.L.S., will shortly be published in about twenty monthly parts. It will give accurate coloured figures of all the species of Rhopalocera found in Europe, showing both the upper and under side where necessary, as well as the differences of sex, if requiring a separate figure; and the most important of the named varieties will, when possible, be also represented. Typical illustrations of larvæ and pupæ will from time to time appear. The figures will be drawn from specimens in the author's collection. The description of a species will, whenever possible, include a notice of its transformation, habitat, and times of appearance, along with the principal synonyms and necessary references. The arrangement and nomenclature will be mainly those of Dr. Standinger's well-known catalogue. Each part will contain four coloured plates and sixteen pages of letterpress. The cost is very moderate. The publishers are Messrs. Reeve and Co., of Henrietta Street, Covent Garden.

The additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius*) from South Africa, presented by Mr. Thornburgh-Cropper; four Harvest Mice (*Mus minutus*), British, presented by Mr. Henry Laver; a Banded Grass Finch (*Poëphila cincta*) from Queensland; two Yellow-bellied Liothrix (*Liothrix luteus*) from India, presented by Mrs. Hylton Joliffe; a Red-legged Partridge (*Caccabis rufa*), European, presented by Mr. Arthur Morrell, School Ship *Cornwall*; a Horrid Rattlesnake (*Crotalus horridus*) from Bahia, presented by Dr. A. Stradling, C.M.Z.S.; a Patas Monkey (*Cercopithecus ruber*) from West Africa, a Blue Jay (*Cyanocitta cristata*) from North America, purchased; a Rhesus Monkey (*Macacus erythræus*), a Cape Buffalo (*Bubalus caffer*), born in the Gardens; seven Australian Wild Ducks (*Anas superciliosa*), five Chiloe Widgeons (*Mareca chiloensis*), a Mandarin Duck (*Aix galericulata*), two Geoffroy's Doves (*Peristera geoffroii*), two Turquoisine Parrakeets (*Euphema pulchella*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN

The Solar Parallax.—At the sitting of the Paris Academy of Sciences on the 6th inst. M. Tisserand communicated a note received from Mr. Todd of the office of the *American Ephemeris* at Washington, giving the value of the solar parallax deduced from the photographic operations of the American expeditions, as detailed in the "General Discussion of Results," a volume which has just been issued. The number of photographs is 213, distributed over various stations thus:—

Northern Hemisphere.		Southern Hemisphere.	
Wladiwostok	13	Kerguelen	8
Nagasaki	45	Hobart Town	37
Pekin	26	Campbelltown	32
		Queenstown	45
		Chatham Island ...	7

Putting dA for the correction of the difference of R.A. between the Sun and Venus, dD for the correction of the difference of declination, and $d\pi$ for that of the assumed value of the parallax (8″·848) the solution of the equations of condition corresponding to the distances gives—

dA = +1″·181 ... dD = +2″·225 ... $d\pi$ = +0″·0397±0″·0418.

Similarly from the equations corresponding to angles of position there result—

dA = +1″·109 ... dD = +0″·637 ... $d\pi$ = +0″·0252±0″·0595.

Combining these values, the final results become—

dA = +0ˢ·076 ... dD = +2″·083 ... $d\pi$ = +0″·035±0″·034,

and the corrected value of the solar parallax is thus 8″·883. It will be seen that the magnitudes of the probable errors are very large in proportion to the corrections obtained.

Biela's Comet in 1805.—Those who have acquainted themselves with the history of this remarkable comet will remember that at its appearance towards the end of 1805 it was last observed in Europe by Thulis at Marseilles on the evening of December 9, at which time it was at its least distance from the earth, and was moving rapidly southwards. The comet was then visible to the naked eye, and it was known that it would probably continue so for some days, and might attract attention in the other hemisphere. But there was no southern observatory in existence at that time. Prof. Hubbard, in his masterly investigation on the motion of Biela's comet, remarked how greatly observations taken in the southern hemisphere at this appearance might have contributed to the progress of the theory of the comet. Gauss was then applying his methods for the determination of elliptic orbits, or rather of orbits without the assumption of a particular conic section, and it could hardly have happened that with good southern observations the nature of this comet's orbit would not have been detected from the observations of 1805, and the comet might thus have been re-observed in 1812, if not in 1819.

Up to a quite recent date it was not known that the comet had been observed in the other hemisphere, but Prof. Winnecke has discovered (where he does not say) some observations made at the Mauritius by MM. Malavois and Dupeloux on December 14 and 15. They were brought to light while he was inquiring into the periodicity of the comet detected at Strassburg by Dr. Hartwig on September 29, 1880, and he gives an account of them in the last number of the *Vierteljahrsschrift der Astronomischen Gesellschaft*. They are entitled "Observations sur la Comète qui a paru à l'Ile de France dans le cours de frimaire au 14ᵉ par M. Malavois et M. Dupeloux." M. Malavois states that he was apprised of the appearance of the comet on the morning of December 14. Four days previously (and therefore the day after it was last seen in Europe) it had been detected by MM. Laprie and Dabadie, the one a censor, the other a professor of the colonial Lycée: they had remarked that it had passed in a very short interval "over the space between the constellations Grus and Pavo, moving almost from north to south." On the evening of December 14 Malavois "avec un excellent sextant à lunettes d'un pied de rayon," measured the distance of the comet from Achernar and Canopus, and the distance between the stars, and Prof. Winnecke has been at the trouble to reduce these observations accurately, and to compare them with Hubbard's elements with the aid of an ephemeris calculated therefrom by Herr Kaufmann. Referring to the above-mentioned periodical for particulars, we may say that Hubbard's orbit is found to place the comet too much to the west by 13′ in right ascension, and in declination one minute to the north. But while giving these differences between calculation and observation, Prof. Winnecke only aims at proving that Biela's comet was recognised in the southern hemisphere, and well observed, considering the means available.

The description of the comet's appearance given by Malavois is worthy of particular remark:—"Cette comète est photosphèrique, c. à d. entourée d'une sphère lumineuse dont le diamètre m'a semblé être en totalité d'environ 45 minutes: mais la partie la plus lumineuse, ou l'auréole vue au commencement du crépuscule du soir n'étoit guère, que de 20 à 25 minutes; on la distinguoit alors très bien, tandis qu'à peine on pouvoit apercevoir les étoiles de 7ᵐᵉ grandeur. La comète vue avec une lunette qui grossit seize fois le diamètre des objets m'a paru divisée en deux par une petite bande obscure; j'ai jugé son diamètre apparent d'environ une minute, mais les bords m'ont semblé confusément terminés et se foudre avec la lumière nébuleuse; une étoile de 4ᵉ à 5ᵉ grandeur que je distinguais très bien dans l'auréole à 4 ou 5 minutes de la comète, s'est trouvée dans une position et une distance différente par rapport à cet astre dont le mouvement propre étoit en effet considérable, comme on la voir." Malavois' observations were limited to the evening of December 14, absence preventing his observing it on the following night, and clouds interfering on December 16 and 17; and he adds: "les jours suivans j'ai cessé de l'apercevoir."

Prof. Winnecke draws attention to the remarkable appearance of the comet under a power of 16, in the evidently small telescope, and asks: "Can we recognise in the 'petite bande obscure,' which divided the head into two parts, the commencement of the action which led to the highly important result, that in 1846 and 1852, instead of a single comet, two were observed, and later the comet has been no longer visible as such." In connection with the Mauritius observation it must be remembered that the aspect of the comet was particularly noted on December 8, when it was nearer to the earth than on December 14, by Olbers, Bessel, and Gauss, who agree in their description: on the same evening it was examined and measured by Schroeter with powerful reflecting telescopes at Lilienthal. Neither observer has any reference to the appearance of a division in the head of the comet on that date. Olbers says "it had a small but very distinctly defined nucleus, surrounded by an extensive nebulosity, without any appearance of a tail." The comet was visible to the naked eye with the brightness of a star of the third or fourth magnitude, and could be well seen after the moon had risen. Schroeter noted that without the telescope it appeared nearly as large as the moon: in his 13- and 15-feet reflectors it was apparently much diminished, his measures giving a diameter of only 5½ minutes: the diameter of the brightest part of the nucleus he found to be 4″·05, and that of the whole nucleus 6″·42; if a division had existed at the date of these measures it is hardly probable that it would have been overlooked by Schroeter. At the reappearance of the comet in 1826, and again in 1832, nothing of the kind was remarked. Hubbard, we know, considered that the division of the comet, from whatever cause it might be produced, took place at the end of the year 1844.

GEOGRAPHICAL NOTES

The hydrographical expedition for the exploration of the mouth of the Obi River has started from St. Petersburg. It consists of four officers of the navy, one astronomer, M. Fuss, and two students of the St. Petersburg University, one of whom is a surgeon and the other a zoologist. Two small steamboats were sent to Perm, on the Kama River, and they will be transported to the Obi.

Herr Siegfried Langer of Vienna is about to undertake an exploring tour in Arabia under the auspices of the Vienna Geographical Society. His researches will be mainly of a linguistic nature, but scientific research is not excluded from his programme; he has prepared himself for the tour during the last few years at the Vienna University.

The geographical department of the British Museum during the past year was deprived of the services of its able curator, Mr. R. H. Major, through ill-health, and on his retirement the opportunity was taken to reduce it to a sub-department. If we may judge by the newly published report of the British Museum, this change has not tended to increase activity in geographical matters, and among the most interesting acquisitions of the past year all that can be mentioned seem to be some old plans of towns and the like.

In the last volume of Consular Reports S. de Zuccato at Venice furnishes an interesting map showing the lines proposed and in course of construction for the completion of the network of railways in Venetia. M. Consul Pernal also contributes a plan of the Havre docks.

It is announced that the Portuguese travellers, Capello and Joens, are about to publish an account of their expedition under the title of "De Benguella as terras d'Iacca." The work will be

issued in parts, and when complete, will form two volumes, illustrated with engravings.

HERR SCHÖLER, who was sent out by the German African Society, has returned to Zanzibar after founding a station at Kikoma.

THE Italian traveller, Piaggia, returned to Khartum on April 30. It is believed there that he will be appointed governor of the Fashoda district, and that the Austrian, Maruo, will become governor of the province of the Blue Nile.

THE Scientific Commission, recently despatched from Paris, has arrived at Zanzibar on its way to examine M. Paiva's vast concession in the Zambesi region, which it is proposed to develop by means of a company. The Commission is to investigate the resources of the territory, chiefly with regard to the mineral wealth supposed to exist there.

PHYSICAL NOTES

A FEW months ago the phenomenon of the "passive state" of iron was examined by M. L. Varenne, who attributed it to the presence of a film of nitrous acid gas upon the surface of the metal. The question has been recently reinvestigated by M. E. Bibart, who finds reason to doubt M. Varenne's conclusions. M. Bibart states that any oxidising agent aids, and any deoxidising agent hinders, the production of passivity.

IN a long memoir presented to the Académie des Sciences by Edmond and Henri Becquerel some very valuable data are given respecting the fluctuations of underground temperatures during 1880 beneath different surfaces. Their observations extended to a depth of 36 metres. The fluctuations were of less extent beneath herbage than below a bare soil, the maxima and minima being more retarded and of less amplitude in the former case. Another interesting point is the protecting effect of a bed of snow. Though the temperature of the air fell to − 15°, and continued below 0° for long periods, that of the surface of the soil was rarely below − 1°, never below − 1°·5.

ACCORDING to Nies and Winkelmann, who have lately studied the expansion exhibited by bismuth, cast-iron, and other metals during their solidification, the specific gravity of bismuth is between 1·031 and 1·0497 times as great in the liquid as in the solid state; a sample whose (solid) density was 10·2 assumed a density of 10·77 when melted. The ratio of the density in liquid state to that in solid state was greater than unity also for the metals tin and zinc, the ratio for tin being 1·0070, and for zinc 1·002. Our readers will doubtless recall the recent experiments of Mr. Wrightson and Prof. Chandler Roberts in the same direction.

HERR STUCKER concludes from experimental inquiry (*Wied. Ann.* No. 5), that the gases chlorine, bromine, and iodine, in regard to thermal behaviour, form a group by themselves among biatomic gases. The ratio of the kinetic energy of the progressive motion of the molecules to the total energy is different for them from that for the others. In their molecules the atoms seem to have a different reciprocal action. From the behaviour of biatomic gases it is inferred that neither Boltzmann's nor Maxwell's supposition as to the nature of the mobility of atoms in the gaseous molecule has a general validity.

WITH regard to the subject of hot ice, Herr Wüllner describes fresh experiments (*Wied. Ann.* No. 5), and he finds that so long as the thermometer-bulb is wholly surrounded with dry ice its temperature does not reach 0°. If the thermometer rises higher, either the bulb is no longer quite covered with ice, or it is surrounded with water, along with a thicker ice-layer. The author's method was to have the thermometer-bulb first coated with ice in a separate vessel; then introduced into the heating-tube and fixed in a caoutchouc stopper; this tube is connected through a tube and spherical vessel with the air-pump, and with the sphere is surrounded with a cold mixture while the vacuum is produced.

THE subject of double refraction of light in moving frictional liquids has been taken up anew by Herr Kundt (*Wied. Ann.* No. 5), using a method which Maxwell did not succeed with, viz., rotation of a cylinder within another cylinder, and sending a beam of polarised light in axial direction through liquid in the annular space. Herr Kundt got positive results in this way with various liquids. 1. The amount of internal friction of liquids is not a certain measurement of the occurrence of double refraction in motion; liquids with small friction giving considerable refraction, and *vice versâ*. 2. The liquids which, with small internal friction, prove doubly refractive, belong to the so-called colloids (gelatine, gum, collodion) or the oils. Solutions of crystalloids did not give the phenomenon by the method described. 3. The double refraction did not markedly affect the rotation of the plane of polarisation in the circularly polarising liquids (but the strongest refraction, it is to be noted, produced a difference of only about half a wave in penetrating a pretty long column of liquid). 4. In collodion-solutions the axes of the double refraction do not lie in the azimuths required by theory. The anomaly was not accounted for. Herr Kundt further offers some general remarks on the relations between the elastic properties of liquids, their coefficients of friction, and the double refraction developed in them.

IT has been hitherto supposed that light directly reflected from a diffraction-grating has the same state of polarisation as light passing through the same plate unruled, or reflected from its smooth surface. Herr Fröhlich now finds, with a very finely-ruled grating, that it is not so. The proof and numerical amount of the difference are indicated in *Wied. Ann.* No. 5.

IN the cold of last winter M. Damien (*Journ. de Phys.*, May investigated the indices of refraction of water under 0° (*i.e.* in surfusion) down to − 8°. He measured the indices corresponding to the three hydrogen lines by the prism method. Starting with a temperature of + 20°, he first confirmed M. Jamin's observation that the passage through the maximum of density does not at all disturb the course of the indices, and he further found that the indices continue to increase below zero, though the density diminishes. The variations of the indices are very small. M. Damien hopes, next winter, to apply the interferential method. (The use of freezing mixtures does not present such favourable conditions as the very slow cooling of the atmosphere.)

RECENT researches by Herren Sohncke and Wangerin on Newton's rings (*Wied. Ann.* Nos. 3 and 4) appear to require a considerable change of ideas as to this phenomenon, and more especially as to the place where interference occurs. The starting-point was an experiment in which the rings produced by a beam of parallel sodium light falling at an angle on a horizontal plate above a plane convex lens were examined with a microscope inclined at the same angle, and capable of being moved horizontally as well as in the direction of its axis. The microscope was first so placed that one part of a dark ring was as sharply defined as possible; the instrument being then moved along to another ring, or another part of the same ring, it was found necessary to move it axially, higher or lower, to get the maximum definition for that part; indicating that the rings do not lie in a horizontal plane, but in some other position. The amounts of axial displacement for different parts of the ring-system were carefully noted. For details of the results we must refer to the original, merely noting, *inter alia*, that the places of interference in the plane of incidence going through the centre of the rings seem to lie in a straight line rising towards the side whence the light comes. In a central plane at right angles to that of incidence, all the places are at the same depth. Herr Sohncke undertook the experimental part in this investigation, while Herr Wangerin has worked out the theory of the phenomena.

ACCORDING to experiments by Herr Kundt (*Wied. Ann.* No. 4), the common surface-tension between liquid and gas decreases considerably with increasing pressure of gas in the case of alcohol, ether, alcoholic solution of calcium-chloride, sulphide of carbon, chloroform, and water. The decrease is greater at low pressures than at high. For a given liquid it varies with the nature of the gas compressed. With alcohol, ether, and alcoholic chloride of calcium solution, air causes a greater decrease of the capillary constant than hydrogen. The decrease is so great with some liquids (*e.g.* ether in air) that probably, with pressures reached without much difficulty, the surface-tension is *nil*, the liquid passing at ordinary temperature into the Cagniard de la Tour state. (The author's experiments were concluded before he knew of Cailletet's experiment, in which a mixture of five vols. of CO_2 and one vol. of air is compressed at a low temperature till the meniscus of CO_2 disappears, and the Cagniard de la Tour state is reached.)

THE ratio of intensity of the two sodium lines has been estimated by Herr Dietrich (*Wied. Ann.* No. 4) using apparatus of great dispersion with a Vierordt double slit giving one spectrum above another, and allowing of displacement, so that one

of the two lines in one spectrum is brought directly over the other in the other spectrum. The photometric parts included a Nicol capable of rotation, a right and left rotating double quartz, and a fixed Nicol. The mean value of the ratio sought, from measurements on three days, was 1·60 ± 0·01; the probable error of an observation being ± 0·032.

THE amount of electric expansion in caoutchouc has been investigated by Herren Korteweg and Julius (*Wied. Ann.* No. 4). They used tubes of white vulcanised caoutchouc made insulating in water by being kept twenty-four hours in oil; the tube was filled with water and placed in a water-bath (to form a condenser), while hydrostatic pressure was varied, and the changes of volume were measured by means of a connected tube-system. The change of volume is shown to be proportional to the square of the striking distance, and inversely proportional to the square of the thickness of tube-wall. It is the same whether the inner liquid be charged negatively or positively. The maximum was reached when the Holtz machine, left to itself, gradually slackened speed till the last spark passed. A table, giving also Quincke's data for glass, shows that both for this and for caoutchouc the volume-changes are, roughly speaking, in inverse ratio of the coefficients of elasticity, so that they must be ascribed to the same cause.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—During the Long Vacation there will be a course of lectures in the University Laboratory by Mr. Fenton, one of the Demonstrators, on Organic Chemistry. The Laboratory will be open for practical work.

During the Michaelmas Term there will be twelve courses of lectures on Chemistry and various branches of Physics, including one by Mr. Shaw on the Conservation of Energy and Theory of Unitation, and a course by Prof. Lewis on the more Common Mineral Rock-Constituents, and another on Descriptive Crystallography by the same.

Prof. Dewar's subject will be Physical Chemistry; and among other advanced lectures will be a course on the General Principles of Chemistry by Mr. Pattison-Muir.

Prof. Hughes and Mr. Tawney will divide between them the work in Geology, Mr. Tawney taking Palæontology in the Michaelmas Term.

Lectures on Botany will be given by Messrs. J. W. Hicks, Vines, Saunders, and Hillhouse. Dr. Vines' lectures in the Michaelmas Term will be on the Physiology of Plants, with practical work, at Christ's College.

Prof. Newton and the Demonstrator of Comparative Anatomy, Dr. Michael Foster, and his corps of lecturers, Prof. Humphry, Mr. Creighton, and Mr. Balfour, will give their usual series of lectures and demonstrations during the Michaelmas Term. Mr. Lea will give advanced lectures on Digestion and Chemical Physiology, and Mr. Langley will lecture on the Histology and Physiology of Muscle, Nerve and the Nervous System.

Dr. Bradbury will lecture on Pathological Anatomy, Prof. Latham on General Therapeutics, Prof. Paget on Clinical Medicine, and Mr. Carver on Clinical Surgery.

The Natural Sciences Tripos, Part I., under the Old Regulations, has just been completed, and the pass-list contains the names of thirty-three men, and three are excused the General Examination. The second part of this examination takes place in December.

The first part of the examination under the New Regulations, by which men can enter for the examination in their second year if they prefer, has just resulted in the publication of a list with five names, in alphabetical order, in the first division, viz. Messrs. Daniels (Trinity), Duncan (Caius), Earl (Christ's), Sherrington (Caius), and Wilberforce (Trinity).

The special examinations in Natural Science for the ordinary B.A. degree have yielded seven men in the first class in Chemistry, and eighteen in the second class. In Geology there was but one man in the first and one in the second class; in Botany, one in the first class; in Zoology, one in the second class.

At Trinity College the prizemen in the June examination in Natural Science were: Third year, Hillier and Ritchie; second year, Daniels and Wilberforce; first year, Davis, Head, Ransom, Thompson. The prizemen at Christ's College are Shipley (first year), Earl (second year), and Parkyn (third year).

The Chancellor of the University (the Duke of Devonshire) has (with the concurrence of Earl Cairns, Chancellor of the University of Dublin) declared that the statutes of Cambridge do not preclude the University from using the Previous and the Tripos Examinations for the purpose of testing the proficiency of women, as sanctioned by the Senate on February 24, 1881.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 19.—"Molecular Magnetism," by Prof. D. E. Hughes, F.R.S.

1. *Influence of an Elastic Torsion upon a Magnetic or an Electric Conducting Wire.*—In my paper of March 7th on "Molecular Electro-Magnetic Induction," I showed that induced currents of electricity would be induced in an iron wire placed on the axis of a coil through which intermittent currents were passing, and that these currents were produced only when the wire was under the influence of a torsion not passing its limit of elasticity. It became evident that if the intermittent magnetism induced by the coil produced under torsion intermittent currents of electricity, an intermittent torsion under the influence of a constant current of electricity or a constant magnetic field would produce similar currents. This was found to be the case, and as some new phenomena presented themselves indicating clearly the molecular nature of the actions, I will describe a few of them directly relating to the subject of this paper.

The apparatus used was similar to that described in my paper of March 7th. An iron wire of 20 centims. was placed in the centre or axis of a coil of silk-covered copper wire, the exterior diameter of the coil being 5½ centims., having an interior vacant circular space of 3½ centims. The iron wire is fastened to a support at one end, the other passing through a guide, to keep it parallel but free, so that any required torsion may be given to the wire by means of a connecting arm or index. A sensitive telephone is in direct communication with the coil, or a galvanometer may be used as the currents obtained by a slow elastic torsion are slow and strong enough to be seen on a very ordinary galvanometer. I prefer, however, the telephone, because it has the intestimable advantage in these experiments of giving the exact time of the commencement or finish of an electric current. It has, however, the disadvantage of not indicating the force or direction of the current; but by means of the sonometer the true value and direction of any current is at once given. The current from a battery of two bichromate cells is sent constantly through the wire if we wish to observe the influence of the torsion of the wire upon the electric current, or a constant field of magnetic energy is given to the wire by either a separate coil or a permanent magnet. The currents obtained in the coil are induced from the change in the molecular magnetism of the wire, but we may equally obtain these currents on the wire itself without any coil by joining the telephone and rheotome direct to the wire; in the latter case it is preferable to join the wire to the primary of a small induction coil, and the telephone and rheotome upon the secondary, as then the rheotome does not interrupt the constant electric current passing through the wire. As the results are identical, I prefer to place the telephone on the coil first named, as the tones are louder and entirely free from errors of experimentation.

If we place a copper wire in the axis of the coil we produce no effect by torsion, either when under the influence of a constant magnetic field or a current passing through it, nor do we perceive any effects if we place an iron wire (2 millims. in diameter), entirely free from magnetism, and through which an electric current has never passed. I mention this negative experiment in order to prove that all the effects I shall mention are obtained only through the magnetism of the wire. If now I pass an electric current for an instant through this same wire, its molecules are instantly polarised, and I have never yet been able to restore the wire to its original condition, and the magnetisation induced by the passage of a current is far more powerful and more persistent in soft iron than tempered steel. This may be due, however, to the fact that in tempered or softened steel we find traces only of a current during the rotation by torsion of its molecules some two to three degrees of sonometer, whilst iron gives constantly a current of 70 sonometric degrees.[1]

In order to obtain these currents, we must give a slight torsion of 5° or 10° to and fro between its zero point. We then have a current during the motion of the index to the right, and a contrary current in moving the index to the left. If we use a

[1] 0·8 of a Daniell battery.

galvanometer, we must time these movements with the oscillations of the needle; but with the telephone it gives out continuous sounds for either movement, the interruptions being only those caused by the rheotome. The direction of the current has no influence on the result; either positive to the free arm or index or negative gives equal sounds, but at the moment of reversal of the current a peculiar loud click is heard, due to the rapid change or rotation of the polarisation of its molecules, and this peculiarly loud momentary click is heard equally as well in steel as in iron, proving that it is equally polarised by the current, but that its molecular rigidity prevents rotation by torsion.

If a new soft iron wire of two millims. (giving no traces of a current by torsion) has passed through it a momentary current of electricity, and then the wire observed free from the current itself, it will be found to be almost as strongly polarised as when the current was constantly on, giving by torsion a constant of fifty sonometric degrees. If, instead of passing a current through this new wire, I magnetise it strongly by a permanent magnet or coil, the longitudinal magnetism gives also 70° of current for the first torsion, but weakens rapidly, so that in a few contrary torsions only traces of a current remain, and we find also its longitudinal magnetism almost entirely dissipated. Thus there is this remarkable difference, and it is that whilst it is almost impossible to free the wire from the influence produced by a current, the longitudinal magnetism yields at once to a few torsions. We may, however, transform the ring or transversal magnetism into longitudinal magnetism by strongly magnetising the wire after a current has passed through it; this has had the effect of rotating the whole of the molecules, and they are all now symmetrical with longitudinal magnetism, then by a few torsions the wire is almost as free as a new wire; and I have found this method more efficacious than heating the wire red hot, or any other method yet tried. If I desire a constant current from longitudinal magnetism, I place at one of the extremities of the wire a large permanent magnet, whose sustaining power is five kilometres, and this keeps the wire constantly charged, resembling in some respects the effects of a constant current. The molecular magnetism or the current obtained by torsion is not so powerful from this, my strongest magnet, as that produced by the simple passage of a current, being only 50 sonometric degrees in place of 70° for that due to the passage of a current. The mere twisting of a longitudinal magnet, without regard to the rotation of its molecule having no effect, is proved by giving torsion to a steel wire strongly magnetised, when only traces of a current will be seen, perhaps one or two degrees, and a constant source of magnetism or electricity then giving no measurable effect.

If we magnetise the wire whilst the current is passing, and keep the wire constantly charged with both magnetism and electricity, the currents are at once diminished from 70° to 30°. We have here two distinct magnetic polarisations at right angles to each other, and no matter what pole of the magnet or of the current the effect is greatly diminished; the rotation of the two polarities would now require a far greater arc than previously. The importance of this experiment cannot as yet be appreciated until we learn of the great molecular change which has really occurred, and which we observe here by simply diminished effects.

If we heat the wire with a spirit flame, we find the sounds increase rapidly from 70 to 90, being the maximum slightly below red heat. I have already remarked in my previous paper this increased molecular activity due to heat, and its effects will be more clearly demonstrated when we deal with the sounds produced by intermittent currents.

2. *Influence upon the Molecular Structure of an Iron or Steel Wire by Electricity or Magnetism.*—Being desirous to modify the apparatus already described, so that it would only give indications of a current if they were of a spiral nature, the wire was kept rigidly at its zero of strain or torsion, and the coil was made so that it could revolve on an axis perpendicular to the wire; by this means, if the wire was free from strain, the centre or axis of the coil would coincide with that of the wire. Thus, with a straight copper wire, we should have a complete zero, but if this wire formed a right or left-handed helix, the coil would require moving through a given degree (on an arbitrary scale) corresponding to the diameter and closeness of the spirals in the helix; the degrees through which the coil moved were calibrated in reference to known copper helices. 50° equalled a copper wire 1 millim. diameter, formed into a helix of 1 centim. diameter, whose spiral turns were separated 1 centim. apart.

In order to obtain a perfect zero, and wide readings, with small angular movement of the coil, it is necessary that the return wire should be of copper, 2 millims. diameter, offering comparatively little resistance, and that it should be perfectly parallel with the steel or iron wire.

The rheotome is joined to a battery of two bichromate cells, and by means of a reversing switch, an intermittent current of either direction can be sent through the wire. The telephone is joined direct and alone to the coil, thus no currents react upon the coil when perpendicular to the iron, and its return wire, if not of a spiral nature.

Placing an iron wire 0·5 diameter, and passing a current through it, I found a change had taken place similar to those indicated in my paper of March 17th; but it was so difficult to keep the wire free from magnetism and slight molecular strains, that I preferred and used only in the following experiments tempered steel wire (knitting-needles I found most useful). All the effects are greatly augmented by the use of iron wire, but its molecular elasticity is so great that we cannot preserve the same zero of reading for a few seconds together, whilst with steel, 0·5 millim. diameter, the effects remained a constant until we removed the cause.

I have not as yet been able to obtain a steel wire entirely free from magnetism, and as magnetism in steel has a remarkable power over the direction of the spiral currents, I will first consider those in which I found only traces. On passing the intermittent current through these, the sounds were excessively feeble for either polarity of current, but at each reversal a single loud click could be heard, showing the instant reversal of the molecular polarity. The degree of coil indicating the twist or spirality of the current was 5° on each side of its true zero. The wire was now carefully magnetised, giving 10° on each side for different currents. The positive entering at north pole indicating 10° right-handed spiral, negative entering the same pole, a left-handed spiral, we here see in another form, a fact well known and demonstrated by De la Rive by a different method, that an electric current travels in spirals around a longitudinal magnet, and that the direction of this spiral is entirely due to which pole of an electric current enters the north or south pole. I propose soon, however, to show that under certain conditions these effects are entirely reversed.

If through this magnetised wire I pass a constant current of two bichromate cells, and at the same time an intermittent one, the spiral is increased to 15°, but the direction of the intermittent current entirely depends on that of the constant current; thus, if the positive of the constant current enters the north pole, the intermittent positive slightly increases the spiral to 17°, and the negative to 13°, both being right-handed; the two zeros of the constant battery are, however, as we might expect from the preceding experiment, on equal opposite sides of the true zero; but if we magnetise the wire whilst a constant current is passing through it, a very great molecular disturbance takes place; loud sounds are heard in the telephone, and it requires for each current a movement of the coil of 40°, or a total for the two currents of 80°. This, however, is not the only change that has taken place, as we now find that both constant currents have a right-handed spiral; the positive, under which it was magnetised, a right-handed spiral of 95°; the negative, a right-handed spiral of 15°, and the true central or zero point of the true currents indicates a permanent spiral of 55°.

This wire was magnetised in the usual way, by drawing the north pole of my magnet from the centre to one extremity, the south from the centre to the other, and this repeated until its maximum effects were obtained; in this state I found, sliding the coil at different portions, that the spiral currents were equal, and in the same direction throughout.

It now occurred to me to try the effect of using a single pole of the magnet; this was done whilst a constant current was passing through the wire, commencing at the extremity, where the positive joined, drawing the north pole through the length of the wire, from positive towards the negative; the effect was most remarkable, as the steel wire now gave out as loud tones as a piece of iron, and the degree on the coil showed 200°. The constant and intermittent currents now showed for either polarity a remarkably strong right-handed twist; the positive 200 right, and the negative 150 right-handed spirals; the molecular strain on its wire from the reaction of the electric current upon the molecular magnetism was so great, that no perfect zero would be obtained at any point, a fact already observed when a wire was under an intense strain, producing

tertiary currents that superposed themselves upon the secondary. In order to compare these spiral currents with those obtained from a known helix, I found that taking a copper wire of similar diameter (0·5 millim.), and winding it closely upon the steel wire ten turns to each centimetre, having a total of 200 turns, with an exterior diameter of 1·5 millims., withdrawing the steel wire, leaving this closely wound helix free, that it gave some 190°, instead of the 200 of the steel wire alone; thus the spiral currents fully equalled a closely wound copper wire helix of 200 turns in a similar length.

If it were possible to twist a magnetised wire several turns to the right, and that its line of magnetism would coincide with that of the twist, then on passing a positive or negative current, there would be an apparent augmented or diminished spirality of the current, but both would have a right-handed twist. The result would be identical with the phenomenon described, although the cause is different.

The explanation of this phenomenon can be probably found in the fact that the constant spirality now observed is that of the electric current under which it was magnetism, for whilst magnetising it we had a powerful source of magnetism constantly reacting upon the electric current, and the constant spirality now observed is the result or remains of a violent molecular reaction at the instant of magnetisation, and the remaining evident path or spiral is that of the electric current. On testing this wire as to its longitudinal magnetic force, I found that it was less than a wire simply magnetised in the usual way; thus the effects are internal, affecting the passage of the electric current, giving, however, no external indications (except apparent weakness) of the enormous disturbance which has taken place.

3. *Molecular Sounds.*—The passage of an intermittent current through iron or other wire gives rise to sounds of a very peculiar and characteristic nature. Page in 1837 first noticed these sounds on the magnetisation of wires in a coil. De la Rive published a chapter in his "Treatise on Electricity" (1853) on this subject, and he proved that not only were sounds produced by the magnetisation of an iron wire in an inducing coil, but that sounds were equally obtained by the passage direct of the current through the wire. Gassiot, 1844, and Du Moncel, 1878–81, all have maintained the molecular character of these sounds. Reis made use of them in his, the first electric telephone invented, and these sounds have been, since the apparition of Bell's telephone, often brought forward as embodying a new form of telephone. These sounds, however, for a feeble source of electricity, are far too weak for any applied purposes, but they are most useful and interesting where we wish to observe the molecular action which takes place in a conducting wire. I have thus made use of these sounds as an independent method of research.

The apparatus was the same as in the last chapter, except no telephone was used. The intermittent electric current was connected by means of switch key, either with the coil inducing longitudinal magnetism in the wire, or could be thrown instantly through the wire itself, thus rapid observations could be made of any difference of tone or force by these two methods; a reversing key also allowed when desired a constant current of either polarity to pass through the wire under observation.

Iron of all metals that I have yet tried gave by far the loudest tones, though by means of the microphone I have been able to hear them in all metals; but iron requires no microphone to make its sounds audible, for I demonstrated at the reading of my paper, March 31st, that these sounds with two bichromate cells were clearly audible at a distance. A fine soft iron wire (No. 28) is best for loud sounds to be obtained by the direct passage of the current, but large wires (1 millim.) are required for equally loud tones from the inducing coil. By choosing any suitable wire between these sizes, we can obtain equal sounds from the longitudinal magnetism or direct current. The wire requires to be well annealed; in fact, as in all preceding experiments, the sounds are fully doubled by heating the wire to nearly red heat. There are many interesting questions that these molecular sounds can aid in resolving, but as I wish to confine the experiments to the subject of the two preceding chapters, I will relate only a few which I believe bear on the subject.

On sending an intermittent electric current through a fine soft iron wire we hear a peculiar musical ring, the cadence of which is due to that of the rheotome, but whose musical note or pitch is independent both of the diameter of the wire and the note which would be given by a mechanical vibration of the wire itself. I have not yet found what relation the note bears to the diameter of the wire; in fact, I believe it has none, as the greatest variation in different sizes and different conditions has never exceeded one octave, all these tones being in our ordinary treble clef, or near 870 single vibrations per second, whilst the mechanical vibrations due to its length, diameter, and strain vary many octaves.

I believe the pitch of the tone depends entirely upon molecular strain, and I found a remarkable difference between the molecular strain caused by longitudinal magnetism and the transversal or ring magnetism produced by the passage of a current, for if we pass the current through the coil, inducing magnetism in the wire, and then gradually increase the longitudinal mechanical strain by tightening the wire, the pitch of the note is raised some three or four tones (the note of the mechanical transversal vibrations being raised perhaps several octaves); but if we tighten the wire during the passage of an electric current through it, its pitch falls some two or three notes, and its highest notes are those obtained when the wire is quite loose. A similar but reverse action takes place as regards torsion; for if the wire is magnetised by the coil we obtain an almost complete zero of sound by simply moving the torsion index 45° on either side, and as this was the degree which gave silence in the previous experiments for the same wire, it was no doubt due to the same rotation of its polarised molecules. If we now pass a constant current through the wire whilst the intermittent one is upon the coil, we hear augmented sounds, not in pitch but loudness, and if we give torsion of 45° to one side we have silence, or nearly so, whilst the other side it gives increased tones which become silence by reversing the battery. If whilst the wire by torsion has been brought to zero, we decrease or increase the mechanical longitudinal strain, then at once the polarised molecules are rotated, giving loud sounds; and we further remark that when the wire is loosened, and we again tighten it, we gradually approach a zero, and on increasing the strain the sounds return; thus we can rotate the molecules by a compound strain of torsion and longitudinal strain.

If we wish to notice the influence of a constant current passing through the wire under the influence of the intermittent current in the coil, we find that if the wire is free from torsion that on passing the current the tones are diminished or increased according to the direction of the current; the tones then have an entirely distinctive character, for whilst preserving the same musical pitch as before, the tones are peculiar, metallic, and clear, similar to when a glass is struck, whilst the tones due to longitudinal magnetism are dull and wanting in metallic timbre. If we now turn the index of torsion upon one side, we have a zero of sound with or without the current; but the opposite direction gives increased tones whilst current is passing through the wire, but zero when not. Here again a peculiarity of timbre can be noticed, as although we have loud tones due only to the action of the current through the wire, the timbre is no longer metallic, but similar to that previously given out by the influence of the coil; evidently then the metallic ring could only be due to the angular polarisation of the molecules, and when these were rotated by torsion the tones were equally changed in its action upon the wire.

I have already shown that a permanent magnet brought near the wire could rotate its polarisation, and it equally can produce sound or silence in these molecular sounds (during that the wire is at its zero of torsion, and a constant current sent through the wire as in the last experiment). We find that either pole of the natural magnet has equal effect in slightly diminishing the sound by an equal but opposite rotation from the line of its maximum effects; but if the wire is brought nearly to zero by torsion, then on approaching one pole of the natural magnet we produce a complete silence, but the opposite pole at once rotates the molecule to its maximum loudness, and on taking away the magnet we have comparative silence as before.

Heating the wire to nearly red heat by a spirit lamp increases the tones of longitudinal magnetism induced by the coil some 25 per cent., but it has a much more marked increase on the tones produced by the direct passage of the current where they have more than 100 per cent. increase; and if we pass the intermittent current through the coil and constant through the wire, we find no direct rotation of the molecules by heat, although an apparent rotation takes place if we by the required torsion first place the wire at its zero. Then on the application of heat faint sounds are heard, which become again almost silent on cooling; this is simply due to the diminution by heat of the effect of the elastic torsion.

Tempered steel gave exceedingly faint tones, requiring the use of the microphone; but on magnetising with a constant current,

inducing spiral magnetism, the sounds became audible, some 15° sonometer against 175° for iron; thus the molecular rigidity of steel as observed by previous methods was fully verified.

I have, I believe, demonstrated by actual experiments which are easy to repeat, that—

1. An electric current polarises its conductor, and that its molecular magnetism can be reconverted into an electric current by simple torsion of its wire.

2. That it is by the rotation of its molecular polarity alone that an electric current is generated by torsion.

3. That the path of an electric current through an iron or steel wire is that of a spiral.

4. That the direction of this spiral depends on the polarity of the current, or that of its magnetism.

5. That a natural magnet can be produced, having its molecular arrangement of a spiral form, and consequently reversed electric currents would both have a similar spiral in passing through it.

6. That we can rotate the polarised molecules by torsion or a compound strain of longitudinal and transversal.

7. That the rotation or movements of the molecules give out clear audible sounds.

8. That these sounds can be increased or decreased to zero by means that alone have produced rotation.

9. That by three independent methods the same effects are produced, and that they are not due to a simple change or weakening of polarity, as when rotation has been incomplete a mere mechanical vibration has at once restored the maximum effect.

10. That heat, magnetism, constant electric currents, mechanical strains and vibrations have all some effect on the result.

Linnean Society, June 2.—Sir John Lubbock, Bart., F.R.S., in the chair.—Mr. R. Romanis of Rangoon was elected a Fellow of the Society.—Dr. G. Hoggan exhibited and made remarks on preparations of the lymphatics of vascular walls.—Mr. Elwes exhibited samples of quinine made by a new process by Mr. Gammie of Sikkim.—Mr. Thos. Christy drew attention to living rubber plants from West Africa, viz., *Urostigma Vogelii* and *Tabernæmontanum crassa*, and he showed products of *Pistacia terebinthus*, viz., the nuts, the resin, and the so-called butter, separated from the resin, and used for sweetmeats in the East, also Chian turpentine from the same tree.—Sir J. Lubbock afterwards read a paper on the habits of ants, for abstract of which see p. 142.—Mr. S. O. Ridley read a paper on the genus *Plocamia* of Schmidt and some other Echinomatous sponges, with reference to the genus mentioned, for which he accepted Prof. Duncan's name of *Dirrhopalum*. He enumerated three species already described, but assigned to other genera, which must be added to it; the distribution is thus extended from the tropical Atlantic to the British, Portuguese and Ceylon Seas. He described a New Zealand species which proves to be new to science and appears to decide a point which has been disputed, viz., the existence of ceratinous material in the skeleton. Geological facts were brought forward showing the existence of the genus in the Eocene, Upper Chalk, and Greensand formations. A new genus of the same order was described, based on a species of Lamarck and two other species; it is closely allied to *Dictyocylindrus*; its distribution extends from Arabia to Australia.—Prof. Duncan also read a communication on two new species of sponges of the genus *Dirrhopalum* from the Atlantic sea-bed.—The ninth part of the Rev. Boog Watson's mollusca of the *Challenger* Expedition, family Pleurotomidæ, was read by the Secretary.

June 16.—Sir John Lubbock, Bart., president, in the chair.—Mr. Alex. Somerville, Capt. J. T. Wright, and Mr. John Forrest, the Australian explorer, were elected Fellows of the Society.—Mr. W. Hood Fitch exhibited a set of folio drawings of new orchids, species of *Odontoglossum*.—The Rev. W. Higgins showed a Holothurian (*Psolus squamatus*) got between the Falklands and Patagonia, originally figured by Otho Fred. Müller in his "Zoologia Danica," and now recorded of wide distribution.—A letter was read from Mr. W. Ferguson of Colombo, mentioning his having found *Wolffia arrhiza*, Wimm., in abundance, and discovery of *Adiantum Æthiopicum*, L., in the Kandyan country, both plants being new to Ceylon.—Mr. J. G. Baker exhibited a specimen of the inflorescence of *Aloe Paryii*, which had flowered for the first time in this country, although the drug obtained from the plant had been known for 2000 years.—Surgeon-Major Aitchison then read a communication on the flora of the Kuram Valley, Afghanistan (Part II.); he showed by a map the peculiarities of the vegetation of the district, and in illustration of his paper referred to a series of dried specimens of the plants and the products in use by the natives, and otherwise characteristically interesting.—The next paper read was on Central African plants collected by Major Serpa Pinto, by Prof. Count Ficalho and W. P. Hiern. The specimens herein discussed were collected by Major Serpa Pinto in the month of August, 1878, along the upper course of the River Ninda, an affluent of the Zambesi, on the west side of the high plateau. As regards the climate of this locality the temperature is described as variable, the weather as very dry during seven or eight months of the year, and very wet during two or three months. The nature of the soil is metamorphic argillaceous schist; the latitude is 14° 46′ S., the longitude 20° 56′ E., and the elevation 1143 metres above the ocean. The rest of the botanical collections made by Major Serpa Pinto at different points of the journey, which were much more considerable, were lost. The present little collection consists of seventy-two numbers, comprising sixty-five species in thirty-nine genera; twelve of these species are new or not previously described and published, and at least one new genus appears amongst them. Some of the specimens are too imperfect for final determination, and several of the grasses and sedges can only be generally referred to their approximate position, and not specifically ascertained. In the case of the previously-known species, the affinities of many of the species are not only with the flora of Huilla in South Angola, but also in several instances with that of extra-tropical South Africa; only a few of the species are widely distributed in the tropics of this and other continents.—There followed a paper by Mr. Edward J. Miers, viz., revision of the Idoteidæ, a family of Sessile-eyed Crustacea; and another by Prof. Ewart on the nostrils of the Cormorant. Certain structural peculiarities in the latter were described, these apparently accounting for or being related to a certain extent with the habit of the bird of flying with its mouth open.

Physical Society, June 11.—Lord Rayleigh in the chair.—New Members: Mr. J. E. H. Gordon and Mr. J. E. Stead, E.I.C.—Prof. Fleming exhibited a new form of B.A. unit-resistance coil devised by him for experiments in the Cavendish Laboratory, with a view to obviate the leakage in the older form due to condensed moisture on the paraffin insulating the electrodes, and also to facilitate the equalisation of the temperature of the coil with the medium it is placed in. For this purpose the wire is wound bare, each layer being insulated from the rest by ebonite fenders nitched to receive the turns, and the coil is inclosed in a brass box screwed together. This box is water-tight, and may be soldered or provided with a leaden washer between the two flanged halves, which screw together. Dr. Stone said he usually insulated the B.A. coil, when plunging it in water, by putting it in a beaker of paraffin oil, which was immersed in turn in the water. Prof. Ayrton pointed out the advisability of makers aiming rather at turning out exact resistances of any definite value, rather than wasting time and increasing the cost of the coils by adjusting them to a given figure, such as 1 or 10 ohms.—Prof. W. Chandler Roberts read a paper on the hardening and tempering of steel. He pointed out that few questions connected with the metallurgy of iron or steel are attracting more attention now than the relation between a metal and the gases it comes into contact with during manufacture. The carburisation of iron has long been of great interest, as shown by the work of Clouet at the end of last century, and that of Margueritte in 1865, who showed that though the conversion of iron into steel could be effected by contact with carbon even in the diamond form, it is nevertheless true that in the ordinary process carbonic acid plays a considerable part which had been overlooked. Graham's 1867 paper on the occlusion of gases by metals gave point to Margueritte's work by showing that carbonic oxide can penetrate to the centre of a mass of iron. It is introduced, in fact, at a comparatively low temperature, while a high temperature is necessary to enable the metal to appropriate the carbon and become steel. Metallurgists are now carefully investigating the effect of occluded gases in iron and steel. Prof. Roberts considered the point recently raised as to whether the hardening and tempering of steel might not be influenced by the occlusion or expulsion of gas. He described experiments by which he proves that, as steel hardens when rapidly cooled *in vacuo*, gases could not play any part in the tempering. He also dwelt on the precautions necessary to keep the metal in the experiment free from occluded gas. He then showed that

Bergman (to whom we owe our knowledge that the difference between wrought iron and steel depends on the carbon in the latter) showed in 1781 that fixed air could give up its carbon to iron; and he concluded by showing that Réaumur, so long ago as 1722, actually employed the Torricellian vacuum in experiments on the tempering of metal, the metal being placed red-hot in a highly rarefied atmosphere. Réaumur also had a clear view of the effect a gas might have on the physical properties of a metal—a point of great interest to physicists in general. Prof. Hughes expressed the opinion that temper was not due to absorption of hydrogen, but to the combination of carbon with the iron. Mr. Stroh had found that an electrically-fused steel contact was glass hard. Prof. Guthrie exhibited a steel chain which he had beautifully blackened by dipping in fused nitre. The skin might be useful in the arts, and was perhaps analogous to that produced by Barff's process. Lord Rayleigh, M. Walenn, Mr. Lecky, Dr. Coffin, Prof. Ayrton, and others continued the discussion.—Mr. Grant then read a paper on curves of electro-magnetic induction, which he had traced out by means of primary and secondary coils, sliding on frames so as to take different positions with respect to one another. The paper was illustrated by experiments and diagrams.—Prof. Reinhold then read portions of a paper by Prof. S. P. Thompson on the opacity of tourmaline crystals. The optical and electric properties of these crystals are related; and Prof. Thomson propounds an explanation of this connection based on the late Clerk-Maxwell's electro-magnetic theory of light. The full paper will be published in the *Journal* of the Society.

Meteorological Society, June 15.—Mr. G. J. Symons, F.R.S., president, in the chair.—Eleven gentlemen were elected Fellows of the Society, viz. F. Crowley, A. M. Davis, Rev. R. Drake, F. H. D. Eyre, W. M. Gibson, E. W. Mathew, J.P., D.L., J. Parnell, M.A., F.R.A.S., J. Rigby, T. G. Rylands, F.L.S., F.G.S., H. Smith, and A. H. Wood.—The following papers were read:—The use of synchronous meteorological charts for determining mean values over the ocean, by Charles Harding, F.M.S.—The climate of Fiji, by R. L. Holmes, F.M.S. This paper gives the results of meteorological observations taken at Delanasau, Bua, Vanua Levu, during the ten years 1871–80.—Note on the formation of hail, by J. A. B. Oliver.—Note on a comparison of maximum and minimum temperature and rainfall observed on Table Mountain and at the Royal Observatory, Cape Town, during January and February, 1881, by John G. Gamble, M.A., M.Inst.C.E., F.M.S.—Mr. E. J. Spitta exhibited and described a new mercurial maximum and minimum registering thermometer.

PARIS

Academy of Sciences, June 13.—M. Wurtz in the chair.—The first volume of Annals of the Rio Janeiro Observatory was presented.—The following papers were read:—On a simple law of natural circular or magnetic double refraction, by M. Cornu. The decomposition of a wave polarised rectilinearly into two waves polarised circularly in opposite directions is such that the mean of the velocities of propagation of the resultant waves is equal to the velocity of the single wave which exists where the causes of decomposition do not act.—On diaidanic alcohol, by M. Wurtz.—On reproduction, by aqueous method, of orthoclase felspar, by MM. Friedel and Sarasin. The felspar was formed at a high temperature in the heart of a mother-water rich in alkaline silicate. The crystals were very small.—Summary account of experiments made at Pouilly-le-Fort, near Melun, on *charbon* vaccination, by M. Pasteur, with MM. Chamberland and Roux. We now possess vaccine matter of *charbon*, capable of preserving from the fatal disease, but not itself fatal, capable of cultivation at will, transportable anywhere without alteration, and prepared by a method which may probably be generalised. M. Milne-Edwards noted the analogy of some of M. Pasteur's facts to the phenomenon of alternating generations, asking whether, by changing the biological conditions, one or other term of such alternation might not be had at will.—Observations on M. Pasteur's paper, by M. Bouley. He calls attention to the successful vaccination, by MM. Arloing, Cornevin, and Thomas, against *symptomatic charbon* (which is distinct from *bacteridian charbon*). They do not use attenuated virus (like M. Pasteur), but natural virus, attenuating the effects by bringing it directly into the blood.—Reply to observations by M. de Lesseps at the last *séance*, by M. Cosson. This relates to the Tunisian Chotts.—On a system of differential equations, by M. Briordier.—On the means of saving water in double locks and acceleration of the service, by M. de Caligny.—M. Milne-Edwards presented a *brochure* on some macruran Crustaceans from great depths in the Caribbean Sea, calling attention, *inter alia*, to a large Crustacean, *Phoberus cæcus*, quite blind, which is a transitional form between groups hitherto thought very different.—M. Fouqué was elected Member in Mineralogy in room of the late M. Delesse.—On linear differential equations with periodical coefficients, by M. Floquet.—On the treatment of vines with sulphide of carbon, by M. Boiteau.—On the functions of two variables arising from the inversion of integrals of two given functions, by M. Fuchs.—On certain systems of differential equations, by M. Halphen.—On the influence of temperature on radiophonic selenium receivers, by M. Mercadier. These tend more or less quickly to a stable state relatively to effects of temperature. At ordinary temperatures and even up to 100° the resistance varies inversely as the temperature. Between 5° or 6° and 35° these variations may be approximately considered proportional one to the other.—On some means and formulæ of measurement of electric elements and coefficients of utilisation with the arrangement having two galvanometers, by M. Cabanellos.—Hemeralopia and retinian torpor, two opposite forms of Daltonism, by MM. Macé and Nicati. Hemeralopia is in general Daltonism for blue. Persons having retinian torpor are as if in a poor light; other rays than the blue are badly perceived, especially the red.—Water-raising machines, by M. de Romilly. He describes a machine, consisting, in its general form, of a shallow cylinder with vertical axis, wide circular opening above, and near the circumference the orifice of a pipe which curves upwards. The cylinder (turbine) is rotated, and the water accumulates by centrifugal force at the circumference, where it leaves tangentially through the pipe. Water can thus be raised much higher than hitherto by centrifugal force (*e.g.* 150 m. with a turbine driven by hand). Two modifications are described. The same principle is applied in oiling the machine.—Cyanides of strontium, calcium, and zinc, by M. Joannis.—Industrial preparation of crystallisable formic acid, by M. Lorin.—Researches on tertiary monamines: I. action of triethylamine on monobromised propylenes, by M. Reboul.—Nervous system of Ophiurans, by M. Apostolides.—On the squamous temporal bone in the vertebrate series, by M. Lavocat.—On *Phytolacca dioica*, by M. Balland.—On the Carboniferous fauna of Rémy (Loire), and its relations with that of Ardoisière (Allier), by M. Julien.—On the dissolution of false membranes of *angina pellicularis* by local applications of papaine, by M. Bouchut.—On an apparatus for suppressing the dangers of movable stoves, by M. Godefroy. The air for combustion is drawn from the chimney itself by a second tube; the chimney and stove may thus be hermetically closed.

ILLUSIONS

Illusions. By James Sully. International Science Series, Vol. xxxiv. (London: C. Kegan Paul and Co., 1881.)

OF the many interesting subjects to which the publishers of the International Science Series have hitherto devoted their volumes, few have presented so formidable a test of the strength of their respective authors as the one which has been assigned to Mr. James Sully. Occupying some of the most obscure regions of physiology, and passing over into the remotest cloudlands of psychology, illusions furnish material alike for the most laborious exploration and the most keen-sighted analysis; but for this very reason they constitute a class of phenomena which invite failure of treatment at the hands of any but the most accomplished psychologist. Mr. Sully is already well known to stand in the first rank as a writer of this class, and the able manner in which he has handled the difficult subject consigned to him shows that it could not have been consigned to a better man. The wide range of his reading, the clearness and force of his style, as well as the soundness of his judgment, give him what we may call exceptional advantages for undertaking a treatise of this kind, while the methodical, not to say laborious, manner in which he has executed the task, shows that he has thrown all his strength into its performance.

First we have presented a "Definition of Illusion," which, standing in a scientific as distinguished from a philosophical treatise, is justly framed so as to exclude any question with the idealist or the sceptic. "For our present purpose the real is that which is true for all. . . . Human experience is consistent; men's perceptions and beliefs fall into a consensus. From this point of view illusion is seen to arise through some exceptional feature in the situation or condition of the individual, which, for the time, breaks the chain of intellectual solidarity which under ordinary circumstances binds the single member to the collective body. Whether the common experience which men thus obtain is rightly interpreted is a question which does not concern us here. For our present purpose, which is the determination and explanation of illusion as popularly understood, it is sufficient that there is a general consensus of belief, and this may be provisionally regarded as at least practically true."

Next we have a very methodical and judicious "Classification of Illusions." As distinguished from hallucinations, illusions "must always have a starting-point in some actual impression, whereas a hallucination has no such basis." Still the one shades off so gradually into the other that no determinate line can be drawn between them. Therefore this distinction, although recognised as a distinction, is not constituted, as it has been constituted by some technical writers, "the leading principle of classification"; but a more popular or common-sense principle is adopted. All immediate knowledge, or knowledge not attained by any conscious process of inference, may be divided into four principal varieties—Internal Perception (Introspection), External Perception, Memory, and Belief, including Unreasoned Expectation. The difficult question as to the relation of Belief to Knowledge is expressly set aside—it being allowed by every one that many of our beliefs are for all purposes of action as good as knowledge. Each of these four sources of immediate or uninferred knowledge is open to the contamination of illusion. Such is notoriously the case with sense-perception, which, as the best-marked variety, is treated first.

In the course of a clear analysis of Perception stress is laid upon what the author calls a "stage of preperception," during which the mind receives the impression of sense, but has not yet interpreted the impression into a coherent percept. "In many of our instantaneous perceptions these two stages are indistinguishable to consciousness . . . But in the classification of an object or the identification of an individual thing there is often an appreciable interval between the first impression and the final stage of complete recognition." [The time, that is, during which, in Mr. Spencer's language, the mind is forming its "integrations"—a process which takes place more rapidly in adults than in children, and in "quick-witted" than in less "ready" individuals.] "And here it is easy to distinguish the two stages of preperception and perception. The interpretive image is slowly built up by the operation of suggestion, at the close of which the impression is suddenly illumined as by a flash of light, and takes a definite precise shape." Now illusions of perception may arise in either of these two stages. Even *in limine* sufficient attention may not be paid to the original impression, and thus a timid man will readily fall into the illusion of ghost-seeing, because too little attentive to the actual impression of the moment. But next, even if the sensation is properly attended to, "misapprehension may arise of what is actually in the mind at the moment." Although this "may sound paradoxical," it means nothing more than that "the incoming nervous process may to some extent be counteracted by a powerful reaction of the centres." Thus, for instance, a sensation of colour may be appreciably modified when there is a tendency to regard it in one particular way.

After giving parenthetically a number of illustrations of errors of perception which have their root in the initial processes of sensation and "preperception," the essay passes on to a further consideration of the more important class of illusions which are connected with the later stages of perception, or the process of interpreting the sense-impression. These misinterpretations of sense-impressions fall into two classes, according as they are connected with a process of *suggestion* or with the process of *preperception*. The illusion of a second shouter in an echo is given as an example of the former, while that of seeing spectres in familiar objects after the imagination has been excited by ghost-stories, supplies an illustration of the latter. The first of these classes of illusions arises from without, the second from within: the one is therefore called Passive, the other Active. Besides these there are other "sub-divisions" which need not here be detailed. Indeed we think that a desirable simplicity of classification might have been attained by ignoring these lesser ramifications, and restricting attention to the main divisions—*i.e.* illusions arising in the initial processes of sensation, in those of preperception, and in those of

perception, passing on to illusions of introspection, memory, and belief.

Taking first the illusions of sensation, preperception, and perception, the following is a brief sketch of Mr. Sully's analysis of their nature and causes.

1. *The Limitation of Sensibility;* the amount of sensation is not always a fair measure of the amount of stimulation, which may be either inadequate or over-adequate in relation to the excitability of the sense-organs. 2. *The Variation of Sensibility;* changes of organic state—whether temporary, as those arising from fluctuating nutrition or fatigue, &c., or permanent, as those arising from age or disease—by supplying us with a variable index of objective phenomena, lead to illusory misrepresentations of these phenomena, unless such variations are duly recognised and allowed for. 4. *Exceptional Relation of Stimulus to Organ;* a man crunching a biscuit can scarcely believe that others do not hear the sound more loudly than he does, or, on rubbing his nose with the points of his third and fourth fingers crossed, that this organ has not become split into two; in such cases the sense perceptions are interpreted by the help of more familiar relations, and so illusion arises. 5. *Exceptional External Arrangements;* unless the fact that we are ourselves moving is clearly presented to consciousness, we instinctively conclude that surrounding objects are moving in the opposite direction, and under similar circumstances are apt to suppose that a train which is just shooting ahead of our own train is moving but slowly; on this principle depends the illusion of the stereoscope, misjudging distances in the clear atmosphere of Switzerland, &c. 6. *Devices of Art;* perspective, effects of light and shade, &c., are all so many devices to ensnare visual perception into a misinterpretation of marks on a flat surface for objects situated in space of three dimensions. 7. *Misconception of Local Arrangement;* the examples given under this head appear to involve exactly the same principle as 5, and nothing more. 8. *Misinterpretation of Form;* the same remark applies to this head—7 and 8 are really species of the genus 5, and ought to have been considered under it. 9. *Illusions of Recognition;* as in general we attend only to what is essential and constant in objects, to the disregard of what is variable or accidental, opportunity is thus furnished for a large class of illusions; imagination and expectant attention likewise play an important part in producing illusions of this kind. 10. *Voluntary Selection of Interpretation.* So far the enumeration has been concerned with what the author calls "Passive Illusions," *i.e.* illusions in which the imagination is inactive, or comparatively so; now we pass to the "Active Illusions," and as an example of voluntary selection of interpretation we may notice that in looking at a geometrical drawing of a truncated pyramid the figure may by a voluntary act be seen to represent alternately a solid upstanding form, or a hollow receding box. 11. *Involuntary Mental Preadjustment;* this resembles the last case, save that the illusion is not due to an act of volition. "The whole past mental life . . . serves to give a particular colour to new impressions. . . . There is a personal equation in perception as in belief." 12. *Sub-expectation;* this has already been alluded to, and is obviously a potent cause of illusion. 13. *Vivid Expectation;* still more obviously so. Indeed vivid expectation may "produce something like a counterfeit of a real sensation." An anxious mother may fancy that she actually hears her child cry in an adjoining room, &c. 14. *Transition to Hallucination;* clearly but a step farther, and illusion passes into hallucination, where imagination has become altogether detached from present surroundings, and has entered on the stage of highest activity. But hallucinations are not invariably of central origin; they may also be of peripheral, and do not always betoken pathological conditions, though they usually reach their highest perfection in the insane Thus there is an apparently unbroken continuity from the scarcely noticeable illusions of normal life leading up to the most startling hallucinations of abnormal. This consideration leads to the following pretty piece of speculation:—

"We may, perhaps, express this point of connection between the illusions of normal life and insanity by help of a physiological hypothesis. If the nervous system has been slowly built up, during the course of human history, into its present complex form, it follows that those nervous structures and connections which have to do with the higher intellectual processes, or which represent the larger and more general relations of our experience, have been most recently evolved. Consequently, they would be the least deeply organised, and so the least stable; that is to say, the most liable to be thrown *hors de combat*. This is what happens temporarily in the case of the sane, when the mind is held fast by an illusion. And, in states of insanity, we see the process of nervous dissolution beginning with these same structures, and so taking the reverse order of the process of evolution.[1] And thus, we may say that throughout the mental life of the most sane of us these higher and more delicately balanced structures are constantly in danger of being reduced to that state of inefficiency which in its full manifestation is mental disease."

Next there follows an interesting chapter on Dreams, in which the mechanism of thought in sleep is ably and suggestively laid bare, so far as the complex and difficult nature of the subject permits. Want of space however prevents our entering upon this chapter, and therefore we shall pass on at once to the Illusions of Introspection. This and the next division of the work is perhaps the part that displays most originality. At first sight it seems almost impossible that the mind could be subject to illusion in its consciousness of its present state or contents; but yet it is clearly shown that such is very frequently the case. "No such clearly-defined mosaic of feelings presents itself in the internal region" as that which is presented in the external when interpreted by sensuous perception; "our consciousness is a closely-woven texture in which the mental eye often fails to detect the several threads or strands." Moreover, "many of these ingredients are exceedingly shadowy, belonging to that obscure region of sub-consciousness which it is so hard to penetrate with the light of discriminative attention." Thus numberless illusions of introspection become possible. All cases of "self-deception" fall into this category, whether they arise from a wrong intellectual focussing of the attention, so as to give undue prominence to some feelings over others, or from a mere emotional bias. As examples we may take the self-deception of a man who is really "bored" by a social entertainment, yet making himself

[1] Reference is there made to Dr. J. Hughlings-Jackson's papers in *Brain*.

believe that he is enjoying it ; or that of a conceited man who thinks more highly of himself than a just introspection, untainted by emotion, would show that he deserves. It is pointed out that illusions of introspection have been more generally recognised by theologians than by philosophers; for while the former preach that the heart mistakes the fictitious for the real, and the evanescent for the abiding, the latter frequently regard a "deliverance of consciousness" as bearing the seal of supreme authority. This consideration leads to an interesting section on "Philosophic Illusions," wherein the question is discussed as to how far the introspective method is a trustworthy one for Philosophy to follow. The result of the discussion is that, as the internal experience of individuals, no less than their common environment, has a common nature, individual introspection should always be guided as much as possible in matters of internal experience by the general consensus; and that "the progress of psychology and the correction of illusion proceed by means of an ever-improving exercise of the introspective faculty."

Coming next to the Illusions of Memory, or Representative as distinguished from Presentative Illusions, it is shown that these are distinct from mere forgetfulness or imperfection of memory. To forget a past event is one thing; to seem to ourselves to remember it when we afterwards find that the event was other than we represented it, is another thing. Illusions of memory are classified under three heads:—(1) *Falsification of Dates;* (2) *Misrepresentation of Events; and* (3) *Creation of Events by the Imagination which never happened in Reality.* Each of these classes of illusory representations has its counterpart in the illusions of Presentation. Thus, Class 1 has its visual counterpart in erroneous perceptions of distance; Class 2 in those optical illusions which depend on the effect of haziness or the action of refracting media; and Class 3 in subjective sensations of light or other hallucinations. In the detailed discussion of Class 1 there is a long and careful analysis of time-consciousness, in which numerous causes of erroneous estimate of duration are clearly stated, after which follows a statement of the conditions leading to *Indefinite Localisation;* these sections are exceedingly good. Under Class 2, or Distortions of Memory, it is shown that although we may in some cases account for the confusion of fact with imagination, "in other cases it is difficult to see any close relation between the fact remembered and the foreign element imported into it. An idea of memory seems sometimes to lose its proper moorings, so to speak; to drift about helplessly among other ideas, and finally, by some chance, to hook itself on to one of these, as though it naturally belonged to it." The analogy between this class of mnemonic illusions and that of illusions of perception is obvious. "When the imagination supplies the interpretation at the very time, and the mind reads this in to the perceived object, the error is one of perception. When the addition is made afterwards, on reflecting upon the perception, the error is one of memory." To the several sources of such mnemonic illusions mentioned by Mr. Sully, I may add another, which I have recently had occasion to observe. This consists in what may be called a transposition of associations. In a club I saw a man walk through the smoking room. He was an eminent psychologist, and although I knew him very well I mistook him for another man equally eminent in the same line, and whom I knew equally well. Clearly the similarity of their pursuits caused a most extraordinary transposition of two sets of associations, for the two men bore no personal resemblance to one another. As soon as the man had left the room, I remembered that I had something to ask the man for whom I had mistaken him. I therefore sent a page to find this other member of the club, but without success. I then went to the hall-porter, who said he was sure that this member had not come in. Yet so strong was my conviction of having seen him that I began to think I must have seen an optical illusion, and therefore resolved to write him a letter to ascertain still more certainly that he had not been in the club at that particular hour. And it was not until I had seriously meditated on the matter for ten or twelve minutes that I suddenly perceived the illusion to have been one of memory and not of sense. This I think is a remarkable case, because both the men in question are so well known to me that I have never ventured to tell either of them of my illusion, lest, psychologists though they be, they should suppose that I had been somewhat excessive in patronising the good things which the club had to afford.

It is shown that Hallucinations of Memory may arise either from believing events in dreams to have occurred in fact, or from waking imagination being strong enough to read spurious facts into the past. The former source is clearly common to us all, and the latter is so far from being distinctive of pathological condition that in one respect, at least, it is even more universally present than the other. For "the total forgetfulness of any period or stage of our past experience necessarily tends to a vague kind of hallucination. In looking back on the past we see no absolute gaps in the continuity of our conscious life." Yet it is obvious that we must fill up immense lacunæ without conscious knowledge, and in so far as this is the case, memory is subject to hallucination. From this position there follows a section on "*Illusions with respect to Personal Identity*," the substance of which may be gathered from the following quotation:—"To imagine that we have ourselves seen what we have only heard from another or read, is clearly to confuse the boundaries of our identity. And with respect to longer sections of our history, it is plain that when we wrongly assimilate our remote with our present self, and clothe our childish nature with the feelings and the ideas of our adult life, we identify ourselves over much. In this way, through the corruption of our memory, a kind of sham memory gets mixed up with the real self, so that we cannot, strictly speaking, be sure that when we project a mnemonic image into the remote past we are not really running away from our true personality."

Lastly, we come to "*Illusions of Belief*," the latter word being taken in its widest sense as embracing all representative knowledge other than memory—including therefore anticipation of the future, acquaintance with the experience of others, and "our general knowledge about things." In so wide a field there is boundless scope for illusions of many kinds. These are classified and considered in the latter part of the work, but we have no space left to follow our diligent author into this division of his subject.

The work concludes with a chapter of "*Results*," which shows that illusion in general consists in a "bad grouping of psychical elements," and as such shade off into fallacies of reasoning; in both there is a want of correspondence between internal and external relations. In the future and for the race natural selection and "direct equilibration" can only be expected to remedy the sources of any such mal-adjustment in so far as it may be of actual injury to life. Thus we can have no absolute criterion of illusion. "Science cannot prove, but must assume the coincidence between permanent common intuitions and objective reality. To raise the question whether this coincidence is perfect or imperfect, whether all common intuitions known to be persistent are true, or whether there are any that are illusory, is to pass beyond the scientific point of view to another, namely, the philosophic." This consideration leads to an exceedingly able statement of the relations between scientific and philosophic thought, but the discussion necessarily runs into an abstruseness that it is not desirable here to enter. In general, however, it may be said that in this, as in some of his other works, Mr. Sully shows that while he has perceived more distinctly than most of our leading psychologists the sharpness of the boundary between science and philosophy, he displays an admirable clearness of thought in never allowing the methods of the one sphere to encroach upon those of the other, while in whichever sphere he chooses to work he enjoys the privilege, almost unique among psychologists, of finding himself equally at home.

GEORGE J. ROMANES

OUR BOOK SHELF

Studies in Biology for New Zealand Students. No. I.—The Shepherd's Purse (*Capsella Bursa-Pastoris*). By F. W. Hutton, Professor of Biology, Canterbury College, University of New Zealand. (New Zealand: By Authority. 1881.)

THIS is a detailed study of the coarse and minute anatomy of a very familiar and widely-diffused weed. A native originally of the palæarctic region, it has now found its way to all temperate climates. It has certainly received at Prof. Hutton's hands, in the Antipodes, a more systematic investigation than ever fell to its lot in Europe. The treatment is much the same as that given to the bean (*Faba vulgaris*) in Huxley and Martin's "Elementary Biology," though with a more botanical bias. The weakest part is the treatment of the root, where nothing is said about the mode of origin of branches. An earlier stage should have been taken, showing the arrangement of the fibro-vascular tissues before they had coalesced into a central cylinder. This however is simply by way of criticism. The method of treatment is excellent, and the Canterbury students are fortunate in being in the hands of a teacher who has such a thorough appreciation of the biological method as applied to botany.

A Text-Book of Indian Botany, Morphological, Physiological, and Systematic. By W. H. Gregg, Lecturer on Botany at the Hugli College. (Calcutta: Thacker, Spink, and Co., 1881.)

THIS is the first eighty pages of a book which, when completed in 500–600, will apparently be practically Henfrey's Elementary Course, adapted to the local requirements of Indian students. There does not seem anything particularly novel or noteworthy in the treatment of the subject, as far as can be judged from the portion printed. As is usual in books of this type, some space is devoted to the Linnean classification. But, as the author points out, there is the excuse that Roxburgh's *Flora Indica*, which is still unsuperseded, is arranged in accordance with it.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

Re W. I. Bishop

I CANNOT but feel greatly surprised that Mr. Romanes, when reporting the result of the investigations made by his colleagues and himself upon the power of "thought-reading" claimed by Mr. W. I. Bishop, should have stated that the letter of introduction which I gave to Mr. Bishop was "doubtless intended to recommend him to the attention of the credulous," since this letter most distinctly expressed my desire to obtain for him "an assemblage of gentlemen specially qualified to appreciate the importance" of what I described in it as (in my judgment) "experiments of great value to the Physiologist and Psychologist." Nor can I see how my having thus recommended "him to the attention of the scientific" is a thing "to be regretted"; since the careful testing of the one set of experiments which Mr. Bishop has shown to Mr. Romanes and his colleagues has resulted in a precise confirmation of my statement that the power of "thought-reading" which he claims is "derived from his careful study of the indications *unconsciously* given by the subjects of his experiments, and from his peculiar aptness in the interpretation of those indications."

What I think "is to be regretted" is that Mr. Bishop did not offer for like careful testing another remarkable set of experiments which he had repeatedly performed in the presence of distinguished medical and scientific men in the United States (from whom he brought introductions to me), and also before a like assemblage in Edinburgh; showing his power of naming words and numbers previously written and sealed up in private, by his acute recognition of indications *unconsciously* given by their writers when the alphabet or digits were "called."

As I have never credited Mr. Bishop with any other power of "thought-reading" than this, I have been surprised to learn that I am accused of "fathering a new humbug."

Another "experiment" which he performed in my own house some time ago struck me as well worthy of careful testing:—

The "subject" of the experiment being asked to draw a card from the pack, to identify it, and then to return it to Mr. Bishop, the latter, after shuffling the pack, dealt out sixteen cards *with their faces downwards*, arranging them in four rows (which I indicate by letters and numbers), as thus:—

	A	B	C	D
E	1	2	3	4
F	5	6	7	8
G	9	10	11	12
H	13	14	15	16

The "subject," having been caused to stand at the table with the cards directly before him, Mr. Bishop, standing at his right side, and taking his right hand into his own left, said to him, "Drop your left hand down on either row (whether *horizontal*, as A, B, C, D, or *vertical*, as E, F, G, H), that you wish taken away." Row B having been selected and taken away, there remained the three rows, A, C, D. "Now," said Mr. Bishop, "drop down on another row." Row D being selected, there remained rows A and C. "Now drop down on a third row." Row A being selected, there remained only row C. "Now drop down upon either the two upper or the two lower cards of the remaining row." The two upper (3 and 7) being selected and taken away, there remained only the two lower (11 and 15). "Now drop down

upon either of the two remaining cards." The lower (15) being selected, and the remaining card (11) being turned up, this proved to be the card originally drawn.

Having seen this experiment twice made successfully with members of my family, I offered myself as the next "subject" of it, with the determination to watch carefully for any manual guidance by which Mr. Bishop might be influencing my choice. The experiment succeeded with me as it had done with my predecessors, and yet I could not, any more than themselves, tell how I was led to make the five successive selections of the cards to be taken away, so as to leave behind the card I had originally drawn.

It may, of course, be assumed that Mr. Bishop knew where he had placed this card, although his "subject" did not; and he informed me that experience has taught him the positions to which the choice of his "subject" can be most easily and certainly guided. The influence of the eyes being excluded by the relative positions of Mr. Bishop and his "subject," the guidance *must* be conveyed through the hand which Mr. Bishop holds in his own; and yet I altogether failed to detect the mode in which it was given.

Of course it may be said that this is only a variation of the conjuror's trick of "forcing" the card which he has determined that the drawer shall choose. (I remember seeing it stated that Louis Napoleon, when Emperor, had defied Houdin then to "force" a card upon him; and that Houdin made him draw the card which in the French pack is designated Cæsar.) But though the same principle of "suggestion" is involved, the conditions under which it acts are altogether different. The conjuror stands *opposite* the drawer, looks at his face as well as at his hand, and continually shifts the position of the cards he holds, so as to prevent a *wrong* card from being drawn, while presenting the *right* one in the manner which he knows by experience to be the most suggestive. But Mr. Bishop does no such thing. The cards remain in their places with their faces downwards; and of the guidance given him by Mr. Bishop standing at his side, the "subject"—even when on the watch for it—remains quite unaware.

If I have made myself understood by your readers, I think I shall have satisfied them that this "experiment" (which may by no means invariably succeed) is of great psychological interest, as showing the large measure in which we may be guided in our choice among things "indifferent," by *influences of which we are ourselves unconscious.* WILLIAM B. CARPENTER

American Meteorological Observations

IN your valued journal (vol. xxiv. p. 16) I find an expression of your regret that it should have been decided that the printing of the *Bulletin* of Simultaneous Meteorological Observations should hereafter take place one year after date, instead of six months. It may be interesting to those of your readers who made use of the *Bulletin* in studying the general atmospheric phenomena of the northern hemisphere, to know that for several years past the data for several distant land stations in Greenland, Iceland, Siberia, Alaska, &c., have been omitted, merely because the mail facilities did not enable us to receive the reports in time for publication in the *Bulletin*. Thus a large portion of the region covered by our maps has been left unrepresented, for which the necessary data come regularly to hand a few weeks or months later. The case is still worse in reference to the marine reports for vessels off on long voyages; for instance, we regularly pay for and receive a large collection of material from the London Meteorological Office that never appears in our published *Bulletin* or charts. The proposed postponement of publication is in fact merely the outcome of several suggestions and recommendations from co-operating nations, in the propriety of which recommendations myself and assistants fully concur.

A Meteor

LAST night, June 24, at 11h. 29m. G.M.T., I observed a meteor, as bright as Jupiter, cross the tail of the great comet 4° or 5° above the head and disappear some 20° to the left, on the vertical of Beta Ursæ Minoris and at an altitude equal to that of the comet's head. It left a bright streak for some seconds. I did not see the beginning, and perhaps not the end, as it may have continued behind a cloud bank. The duration for the above path was three seconds, determined afterwards by experiment. Place of observation, lat. 51° 32′, long. 0° 11′ W.

G. L. TUPMAN

27, Hamilton Terrace, St. John's Wood, June 25

LOOKING at the comet last night from my garden at 11.25 p.m. I saw a large meteor pass nearly horizontally from a little east of north to within a short distance of the comet, rather above the head. It was as large as Venus when brilliant, but with a red or orange tinge. The motion was rather slow. A.

Adsett Court, Westbury-on-Severn, June 25

Earthquake in Van

IT may perhaps be considered worthy of a note in your columns that an earthquake was experienced in this neighbourhood on Monday, May 30, at a few minutes before 6 a.m.

Here in Van the shock was slight, consisting only of a tremulous motion lasting a few seconds; but I have to-day received information that at Bitlis the shock was so severe as to cause people to rush out of their houses in fright, and that a village named Téout, situated near the western shore of the Lake of Van, was destroyed by it, with the loss of a considerable number of lives. I have as yet heard no details, but if any further circumstances of interest should come to light I will communicate with you again.

It is well known that the environs of the Lake of Van show many signs of ancient volcanic action; at least three volcanoes with distinct craters forming prominent features on or near its shores. Of these the Nimroud Dagh, on the western shore of the lake, is said by tradition to have been active not more than 400 years ago. It contains an immense crater five or six miles across, in which are situated hot springs. The village Téout which has been destroyed lies at the foot of the eastern slopes of this mountain. EMILIUS CLAYTON

Van, Turkey in Asia, July 6

Freshwater Actineæ

I YESTERDAY noticed in a small *freshwater* aquarium four specimens of a small freshwater Actinia of a very pale olivaceous colour. They have each six tentacles more than 1 inch in length when fully extended, but then so extremely fine at the ends as to be almost invisible. The body or stalk is about 0·1 inch long by 0·05 inch in diameter when at rest, and about 0·5 inch long and 0·015 inch in diameter when expanded.

I was not aware before of the existence of freshwater Actinia, but as the specimens to which I now refer are in all respects similar to sea-anemones, there can be no doubt on the subject.

I have succeeded in transferring two specimens, which have duly rooted and expanded themselves in a bottle and a tumbler, and I shall be happy, if they are of sufficient interest, to send one to your office or elsewhere for inspection. W. SEDGWICK

Royal Naval School, New Cross, June 24

The Observation of Hailstorms

IN the most casual survey of the literature relating to the phenomenon of hail one cannot fail to be struck with the remarkable contradictions which everywhere make themselves apparent. Some writers say that hail falls oftenest in the tropics; others assert that it is altogether unknown there! Howard states that the maximum hailfall in this country occurs in the summer season, while Dalton and others say that it is in winter. I think these singular discrepancies are attributable, in many cases at least, to imperfect observations. Most of the meteorologists who have given special attention to the phenomenon of hail have had their pet theories, and naturally their observations have been guided to a considerable extent by the requirements of the particular theories which they advocated. Thus we find Kämtz ascribing the formation of hail to the conflict of opposing currents of wind, Volta to the electrical condition of two separate layers of cloud, Leslie to the presence of strata of air at different temperatures, von Buch to ascending currents of air, and so on, all which theories are based, not upon invariable phenomena, but upon isolated features which happen to have come repeatedly under the notice of those particular observers in the particular hailstorms which they witnessed. I think it would enhance the

value of observations in some degree if all those who have opportunities of making them would draw up their notes on some regular and uniform plan. I do not presume to submit a scheme, but would suggest the following points as being of some importance :—

1. Date, and hour of the day.
2. Area of storm. If it assume the tornado form, give (*a*) length of the course, (*b*) breadth, (*c*) direction of motion, (*d*) rate of progression.
3. Physical features of the locality—(*a*) elevation, (*b*) mountains and plateaux, (*c*) rivers and valleys, (*d*) forests, &c.
4. Temperature (*a*) before the storm, (*b*) after the storm, and if possible to be observed (*c*) changes during the storm.
5. Barometrical readings (frequently taken during time of hailstorm).
6. Wind—(*a*) direction near the earth's surface, (*b*) direction in the higher regions as indicated by the cloud motion, (*c*) force.
7. Preceded or followed by rain.
8. Aspect of the clouds. Note if there be any appearance of two separate strata at different elevations.
9. Electrical phenomena. Should there be lightning, note the relation between the discharges and the fall of the hail—whether the lightning precede the hail, or *vice versâ*.
10. Duration of the storm at one spot.
11. Sound. Note if a peculiar noise precede the descent of hail.
12. Conformation and size of the hailstones.
13. General character of the weather before and after the storm.

Notes.—(1) The precise date of a hailstorm is an important point, as it determines the period of their occurrence. Respecting the *annual* period we have the most conflicting testimony. Shortly after the establishment of hail insurance companies valuable statistics were published by those bodies. From particulars furnished by the Farmers' Insurance Institute the following table was drawn up :—

Hailstorms in	January	0
,,	February	1
,,	March	2
,,	April	3
,,	May	7
,,	June	10
,,	July	17
,,	August	4
,,	September	2
,,	October	0
,,	November	0
,,	December	0
		46

Dalton gives the following as the result of five years' observations :—

In	January it hailed on	11	days.
,,	February	7	,,
,,	March	5	,,
,,	April	8	,,
,,	May	11	,,
,,	June	6	,,
,,	July	2	,,
,,	August	1	,,
,,	September	6	,,
,,	October	7	,,
,,	November	7	,,
,,	December	13	,,

Giddy thus sums up twenty-one years' observations at Penzance :—

January	23	July	1
February	25	August	0
March	25	September	5
April	27	October	17
May	7	November	22
June	5	December	43

Thomson ("Introd. to Met." p. 174) gives the following as the relative proportions :—

Winter to all the other seasons as		45·5 to 54·5
Spring	,, ,,	29·5 to 70·5
Autumn	,, ,,	22·0 to 78·0
Summer	,, ,,	3·0 to 97·0

From a comparison of these tables we see that Dalton, Giddy, and Thomson agree in making winter the season of maximum hailfall, while the insurance statistics point to the opposite conclusion, the hailstorms in June and July being much in excess of those in the other months of the year. I strongly suspect however that Dalton, and other observers who have arrived at similar results, included in their enumeration of hailfalls what we may call, in absence of a better name, *winter hail*. It is very unfortunate that the word *hail* has in our language been used to denote two entirely different phenomena, the French *grêle*, or hail proper, and *grésil*, or that small round powdery snow which often falls towards the end of a snowstorm and in the early part of a very frosty night. *Grésil* has nothing in common with *grêle*. The one falls exclusively in winter, and the other, I venture to say, as exclusively in summer.

(6) Dalton observed that the winds which brought hailshowers in the north of England were always south-west, west, or north-west. The wind often shifts erratically. Howard mentions a hailstorm during which it was first east, then south, afterwards west, again east, and finally west. Beccaria makes the following singular statement :—"While clouds are agitated with the most rapid motions, rain generally falls in the greatest plenty; and if the agitation be very great, it generally hails."

I shall be glad to receive references to memoirs and papers on the subject of hail, also particulars of storms, from any of your readers who have them at hand. J. A. B. OLIVER

Athenæum, Glasgow, June 6

How to Prevent Drowning

IN the discussion that Dr. MacCormac's letter has elicited, the essential principle upon which the whole art of swimming is fundamentally based appears to have been overlooked. As Dr. MacCormac says, the human body naturally floats in water, and freely so in salt water; but *how* does it float, supposing the necessary condition of buoyancy, the inflation of the lungs, is maintained? If the limp, dead body of a man is thrown into water in this condition it floats with the head and face immersed, but with that part of the back just between the shoulders upwards, and just bobbing out of water. This is a drowning position, and the first business of swimming is to counteract the tendency to this position, that is, to balance the body in such wise that the head shall be upwards and the lower part of the face uppermost, in spite of the natural tendency of the head to sink, it having a greater specific gravity than water, or the average of the whole body. Dr. MacCormac, in his letter (p. 166), says that "it is just as easy, if we only knew it, to tread water as to tread earth." Quite so; but it is also about as difficult. No human being can "tread earth" without training, the principal effort in this training being directed to keeping the centre of gravity within the base covered by the soles of the feet; and in like manner we must learn to keep the centre of gravity of the body and the centre of its buoyancy in a perpendicular line with mouth and nostrils in the air. I have been a swimmer since I was eight years of age, and consequently swim as naturally as I walk, and float easily in fresh or salt water, without any treading or paddling of any kind; but though I can thus lie basking luxuriantly and motionless, I am just as unable to sleep floating as to sleep standing upright. I have often tried, and immediately I begin to doze my mouth is under water. The effort of keeping the face upwards is as automatic and unconscious as that of standing still on the ground, but there is an effort of balancing nevertheless.

I have taught many to swim, and my first lesson is on balancing the body; the easiest formula for attaining this power is to *keep the hands down and look at the sky* while the chest is expanded as much as possible by throwing the shoulders well back in military attitude. Any man or woman of ordinary specific gravity who can do this can float *and breathe*, but to do it, simple as it is, requires practice or training, physical training of the muscles, and cerebral training in order to acquire that command of all the faculties without which there can be no treading of water or other device for keeping the mouth and nostrils in the air. If this were taught, not on paper, but in the water, to everybody, Dr. MacCormac's object would be attained. As it is, the human being compared with four-legged animals is relatively as inferior to them in water as it is on land. The calf or the colt walks a few minutes after it is born, the kitten or puppy in a few days; but the human infant only after many months. W. MATTIEU WILLIAMS

Royal Polytechnic Institution, June 27

Buoyancy of Bodies in Water

IN NATURE, vol. xxiv. p. 166, Dr. W. Curran says:—"It is, I think, generally assumed in books and courts of law that all bodies, human and bestial, sink as a rule in water as soon as life is extinct." How far this statement may be true as regards animals generally, I am not prepared to say, but it certainly does not hold good as regards the reindeer. The Eskimos spear many reindeer whilst crossing lakes, and it sometimes occupies them an hour or two in "towing" them all to land, yet it is a rare exception that any are lost by sinking, even of the full-grown males, which in autumn are heavily weighted with large antlers.

An Optical Illusion

WILL you allow me to add something to the letter from William Wilson in NATURE, vol. xxiv. p. 53.

1. The results described may be produced without bending the card or using a square hole. A flat card, with a pin-hole, is held some distance from the eye, and a pin moved so as to be in a right line between the eye and the hole; the results described by Mr. Wilson follow. 2. Some few trials may be necessary in order to get a clear image (if this is the proper term), but it will be found that considerable variation in the distances from the eye to the pin and from the pin to the hole can occur without destroying the effect. 3. The image seems to me to be close to the card in every case, while the distance from the eye to the card may vary a great deal. CLARENCE M. BOUTELLE

State Normal School, Winona, Minn., U.S., June 10

Resonance of the Mouth-Cavity

IN reply to Mr. George J. Romanes, I beg to say that the object of my communication printed in NATURE, vol. xxiv. p. 100, was to show that the mouth-cavity will give a distinct resonance to different rates of vibration *already in the air* by being shaped suitably for each of them (and providing they come within its limit). The mouth thus gives the means of analysing the composite nature of sound. Any one successfully repeating my experiments given on pp. 100, 126, would be satisfied that they pointed to something different to the boys' amusement mentioned in Mr. Romanes' letter (p. 166).

5, West Park Terrace, Scarborough JOHN NAYLOR

American Cretaceous Flora

IN several of the interesting and valuable papers on the Tertiary flora which Mr. J. Starkie Gardner has contributed to the English journals he has referred to the fossil plants in our Cretaceous rocks as representing a flora really Tertiary in character; and, influenced by the modern aspect of the plants contained in our Dakota group (Lower Cretaceous), he has expressed a doubt whether even that should be regarded as truly of Cretaceous age. In a former number of NATURE I endeavoured to show that our Dakota flora was Cretaceous, inasmuch as it is found in rocks which are overlain by several thousand feet of strata containing many mollusks, fishes, and reptiles which are everywhere recognised as Cretaceous, and none that are Tertiary.

Mr. Gardner was not however convinced by my facts or arguments, and in the April number of the *Popular Science Review* he reiterates and emphasises his formerly expressed opinion, referring all our Cretaceous strata to the Maestricht beds, and intimating that, in common with that formation, they should be separated from the Cretaceous system. His language is as follows:—

"The presence of *Mosasaurus* in the Maestricht beds, and the far newer aspect of its fauna, show that it must have belonged to an altogether different period, probably the one represented in America by a great so-called Cretaceous series containing a mixture of Cretaceous and Tertiary mollusks, dicotyledonous plants, and *Mosasaurus*. . . . .

"No American or European so-called Cretaceous land flora can be proved to be as old as our White Chalk."

Now in no spirit of criticism, for I appreciate and value the excellent work that Mr. Gardner is doing, but simply for the vindication of the truth of geology, I ask him to qualify these statements.

I am impelled to this course by the following facts:—

In our Triassic series we have in some places beds of coal and the remains of a vegetation decidedly Mesozoic in character, consisting of Cycads, Conifers, and Ferns, but, as far as we yet know, without a single Angiosperm.

In the Jurassic age the eastern half of the North American Continent formed a land-surface, for the sediments of the Jurassic sea are confined to a somewhat irregular area in and west of the Rocky Mountain belt.

Of the Jurassic flora of North America we as yet know little or nothing; but the continent that bordered the Jurassic sea ultimately became covered with a new, varied, and highly-organised flora, of which the origin is yet unknown.

In the Cretaceous age all the continent lying east of the Wasatch Mountains was affected by a subsidence which brought the sea in from the Gulf of Mexico with a front 1000 miles wide, and the great inland sea thus formed gradually extended northward till it reached nearly, if not quite, to the present shore of the Arctic Ocean.

The waves of the Cretaceous sea in their advance swept before them a shore that was covered with a luxuriant forest of at least one hundred species of Angiospermous trees; and the remains of trunks and twigs, leaves and fruit, were buried up in the sheet of beach material which accumulated all along the advancing shore line, and which now forms the Sandstones of the Dakota group. Up to the present time very few mollusks have been found in this group, and they are not sufficient to fix with exactness its relation to the Cretaceous series of other countries. The plants, too, are distinct from any found in Europe, though they include, with many extinct forms, genera which are common in the living forests of America, such as *Quercus salix*, *Magnolia*, *Fagus*, *Liquidambar*, *Liriodendron*, &c.

When the subsidence which produced the Dakota group was at its maximum the sea stood several thousand feet deep over the central portion of the trough between the Alleghanies and the Wasatch Mountains, and here we now find at least two thousand feet of marine, calcareous, organic sediment, which have furnished hundreds of species characteristic of the Cretaceous age, and a large number that are identical with those contained in the Upper Greensand and Chalk of Europe.

It is true that up to the present time no Neocomian fossils have been found in the interior of the Continent, but with that exception the entire Cretaceous series of the Old World is represented there. Hence it is not true that our Cretaceous "contains nothing so old as the Chalk."

Nor is it true, as intimated by Mr. Gardner, that our "so-called Cretaceous rocks" contain a Tertiary flora and fauna, as no Tertiary species of either has yet been found there. The flora of the Dakota group is more modern in its aspect than that of the Lower and Middle Cretaceous of Europe, but its plants are specifically different from any found in Europe in our Middle Cretaceous (Colorado group), Upper Cretaceous (Laramie group), or Tertiary beds (of Green River, Fort Union, and Oregon). The facts apparently indicate that the earliest development of Angiospermous plant-life took place here, and this in a *temperate flora* of which the descendants long afterwards—in Tertiary times—occupied Greenland, Spitzbergen, &c., and spread by land connections into Europe and Asia.

The best authorities we have had on questions relating to the Cretaceous fauna—Messrs Gabb and Meek—were fully agreed in regarding our Middle Cretaceous as of the age of the Chalk. Mr. Gabb divided the Cretaceous series of California into four members—

1. The Tejou group.
2. The Martinez group.
3. The Chico group.
4. The Shasta group.

Of these the oldest, or Shasta, group was regarded by him as of Neocomian age, the Chico and Martinez groups—which should perhaps be united—as the representatives of the Upper and Lower Chalk, and the Tejou group as the equivalent of the Maestricht beds.

The coal-beds and the fossil plants of Vancouver's Island lie at the base of the Cretaceous series as it exists there, and the molluscous remains indicate that it is the equivalent of the Chico group. The plants are apparently all distinct from those of the Dakota group of the interior. They include palms and cinnamons, and evidently grew in a warmer climate than that which produced the temperate flora of the Lower Cretaceous of Kansas, Nebraska, and the Atlantic coast.

Among the Vancouver Island Cretaceous plants is one well-known species, *Sequoia Reichenbachii*, H., which is found in

various localities in the Upper Greensand and Chalk of Europe, and also occurs at Kome.

The fossils collected by Mr. Richardson on Queen Charlotte's Island have been shown by Mr. Whiteaves to represent the very base of the Cretaceous series, and to include some forms that are rather Jurassic than Cretaceous. The plants of this group, though few and imperfect, seem to be chiefly Conifers, as in the oldest Cretaceous flora of Europe.

Our present knowledge of the age of the American Cretaceous flora may then be epitomised as follows:—

1. The oldest Cretaceous rocks known in North America, those of Queen Charlotte's Island, represent the Neocomian of Europe, and have so far furnished no Angiospermous plants.

2. The Shasta group of California, supposed to be the equivalent of the upper part of the Neocomian, has yielded no plants.

3. The coal-strata and plant-beds of Vancouver's Island, probably a little later than the Dakota group of the interior, contain many Angiosperms, and are of the age of the Gault or Upper Greensand. Lesquereux's identification of Vancouver's Island plants in the Laramie of Colorado and Eocene of Mississippi is evidently a mistake. There are no species common to these very distinct formations.

4. The Dakota group, the mechanical base of the Cretaceous series of the interior of the continent, which has yielded at least 100 distinct species of Angiospermous woody plants, is certainly older than the Chalk of the Old World.

5. The Raritan sands and Amboy clays of New Jersey, the lowest members of the Cretaceous on the Atlantic coast, contain a flora not less rich than that of the Dakota, with which it has a few species in common. This group of plants has not yet been described, but a large number of specimens are in my hands, from which drawings and descriptions are being made for the State of New Jersey. The flora is that of a temperate climate, consisting mainly of Angiosperms, but it also includes many beautiful Conifers.

6. The Colorado group, or great series of marine Cretaceous beds of the interior of the Continent, represents the strata known in the Old World as the Gray and White Chalk, and the Maestricht beds. Few plants have been obtained from this group in the United States, but I am informed by Dr. Dawson that an interesting collection of plants has been obtained from it on Peace River, in Canada. These will soon be described by him.

7. The Laramie group, or "Lignite series" of the central part of the continent, underlies unconformably the Coryphodon beds, the base of the Eocene, and is in my opinion the upper member of the Cretaceous system. Many of its plants have been described by Mr. Lesquereux in his "Tertiary Flora," but so far as my observation extends it contains no species identical with any found in unmistakable Tertiary rocks.

School of Mines, New York, May 20 J. S. NEWBERRY

GEORGE ROLLESTON, M.D., F.R.S.

PROF. ROLLESTON'S death, which took place at Oxford on June 16, and which we briefly announced in our last number, may well be called premature, as he was in the prime of life, and but a few months ago seemed to all, except a few closely observant intimate associates, still in the plenitude of his powers, and capable of much good work in time to come.

The son of a Yorkshire clergyman, he was born at Maltby on July 30, 1829, and had therefore not completed his fifty-second year. His early aptitude for classical studies, carried on under the instruction of his father, must have been most remarkable if, as has been stated in one of his biographies, he was able at the age of ten to read any passage of Homer at sight. He was not educated at one of the great public schools, but entered at Pembroke College, Oxford, took a First Class in Classics in 1850, and was elected a Fellow of his College in 1851. He then studied medicine at St. Bartholomew's Hospital, joined the staff of the British Civil Hospital at Smyrna during the latter part of the Crimean war, was appointed assistant-physician to the Children's Hospital in London, 1857, but took up his residence again at Oxford in the same year on receiving the appointment of Lee's Reader in Anatomy at Christ Church. In 1860 he was elected to the newly-founded Linacre Professorship of Anatomy and Physiology, which he held to the time of his death. He was elected a Fellow of the Royal Society in 1862, and a Fellow of Merton College, Oxford, in 1872. He was a member of the Council of the University, and its representative in the General Medical Council, and also an active member of the Oxford Local Board.

In 1861 he married Grace, daughter of Dr. John Davy, F.R.S., and niece of Sir Humphry Davy, and he leaves a family of seven children.

The duties of the Linacre professorship involved the teaching of a wide range of subjects included under the terms of physiology and anatomy, human and comparative, to which he added the hitherto neglected but important subject of anthropology, as well as the care of a great and ever-growing museum. In the present condition of scientific knowledge it requires a man of very versatile intellect and extensive powers of reading to maintain anything like an adequate acquaintance with the current literature of any one of these subjects, much more to undertake original observations on his own account. Even a man of Rolleston's powers felt the impossibility of any one person doing justice to the chair as thus constituted, and strongly urged the necessity of dividing it into three professorships, one of physiology, one of comparative anatomy, and one of human anatomy and anthropology. The work which he did however contrive to find time to publish, and by which he will be chiefly known to posterity, is remarkable for its thoroughness. He never committed himself to writing without having completely mastered everything that had been previously written upon the subject, and his memoirs bristle with quotations from, and references to, authors of all ages and all nations. The abundance with which these were supplied by his wonderful memory, and the readiness with which, both in speaking and writing, his thoughts clothed themselves with appropriate words, sometimes made it difficult for ordinary minds to follow the train of his argument through long and voluminous sentences, often made up of parenthesis within parenthesis.

The work which was most especially the outcome of his professorial duties is the "Forms of Animal Life," published at the Clarendon Press in 1870. Though written chiefly with a view to the needs of the university students, it is capable of application to more general purposes, and is one of the earliest and most complete examples of instruction by the study of a series of types, now becoming so general. As he says in the preface, "The distinctive character of the book consists in its attempting so to combine the concrete facts of zootomy with the outlines of systematic classification, as to enable the student to put them for himself into their natural relations of foundation and superstructure. The foundation may be wider, and the superstructure may have its outlines not only filled up, but even considerably altered by subsequent and more extensive labours; but the mutual relations of the one as foundation and the other as superstructure which this book particularly aims at illustrating, must always remain the same."

Besides this work, Prof. Rolleston's principal contributions to comparative anatomy and zoology are the following:—"On the Affinities of the Brain of the Orang Utang," *Nat. Hist. Review*, 1861; "On the Aquiferous and Oviductal System in the Lamellibranchiate Molluscs" (with Mr. C. Robertson), *Phil. Trans.* 1862; "On the Placental Structures of the Teurec (*Centetes ecaudatus*) and those of certain other Mammals, with Remarks on the Value of the Placental System of Classification," *Trans.* Zool. Soc. 1866; "On the Domestic Cats of Ancient and Modern Times" (*Journal of Anatomy*, 1868); "On the Homologies of Certain Muscles Connected with the Shoulder-Joint" (*Trans.* Linn. Soc., 1870); "On the Development of the Enamel in the

Teeth of Mammals" (*Quart. Journ.* Micros. Soc., 1872); and "On the Domestic Pig in Prehistoric Times" (*Trans.* Linn. Soc., 1877).

Latterly he did much admirable work in anthropology, for which he was excellently qualified, being one of the few men who possess the culture of the antiquary, historian, and philologist on the one hand, and of the anatomist and zoologist on the other, and could make these different branches of knowledge converge upon the complex problems of man's early history. The chief results of his work of this nature are contained in his contribution to Greenwell's "British Barrows" (1877), a book containing a fund of solid information relating to the early inhabitants of this island. In this department of science Prof. Rolleston stood almost alone in this country, and we know of no more fitting tribute which the University of Oxford could pay to his memory than to found a chair of anthropology, a subject in the cultivation of which England is fast being outstripped by every other civilised nation. His last publication, and one which is on the whole the most characteristic as exhibiting his vast range of knowledge on many different subjects, was a lecture delivered in 1879 at the Royal Geographical Society on "The Modifications of the External Aspects of Organic Nature produced by Man's Interference."

That Dr. Rolleston has not left more original scientific work behind him is easily accounted for by the circumstances under which he lived at Oxford. The multifarious nature of the subjects with which the chair was overweighted; the perpetual discussions in which he was engaged consequent upon the transitional condition of education both at Oxford and elsewhere during the whole term of his office; the immense amount of business thrust upon him, or which he voluntarily undertook, of the kind that always accumulates round the few men who are at the same time capable and unselfish, such as questions pertaining to the local and especially the sanitary affairs of the town in which he lived, or connected with the reform of the medical profession, both in and out of the Medical Council, which constantly brought him to meetings in London; his own wide grasp of interest in social subjects, and deep feeling of the responsibilities of citizenship, and his sense of the duties of social hospitality, which made his house always open to scientific visitors to Oxford; all these rendered that intense concentration requisite for carrying out any continuous line of research impossible to him.

He was often blamed for undertaking so much and such diverse kinds of labour, so distracting to his scientific pursuits; but being by constitution a man who could never see a wrong without feeling a burning desire to set it right, who could never "pass by on the other side" when he felt that it was in his power to help, nothing but actual physical impossibility would restrain him. For several years past, when feeling that his health and strength did not respond to the strain he put upon them, he resorted to every hygienic measure suggested but one, and that the one he most required, rest; but this he never could or would take. During the last term he spent at Oxford, before his medical friends positively forced him (though unfortunately too late) to give up his occupations and seek change in a more genial climate, he was working at the highest pressure, rising every morning at six o'clock, to get two uninterrupted hours in which to write the revised edition of the "Forms of Animal Life" before the regular business of the day commenced.

It is impossible for those who had no personal knowledge of Rolleston to realise what sort of a man he was, and how great his loss will be to those who remain behind him. No one can ever have passed an hour in his company, or heard him speak at a public meeting, without feeling that he was a man of most unusual power, of lofty sentiments, generous impulses, marvellous energy, and wonderful command of language. In brilliant repartee, aptness of quotation, and ever-ready illustration from poetry, history, and the literature of many nations and many subjects, besides those with which he was especially occupied, he had few equals. "In God's war slackness is infamy" might well have been his motto, for with Rolleston there was no slackness in any cause which he believed to be God's war. He was impetuous, even vehement, in his advocacy of what appeared to him true and right, and unsparing in denunciation of all that was mean, base, or false. To those points in the faith of his fathers which he believed to be essential he held reverently and courageously, but on many questions, both social and political, he was a reformer of the most advanced type. Often original in his views, always outspoken in giving expression to them, he occasionally met with the fate of those who do not swim with the stream, and was misunderstood; but this was more than compensated for by the affection, admiration, and enthusiasm with which he was regarded by those who were capable of appreciating his nobility of character. The loss of the example afforded by such a nature, and of his elevating influence upon younger and weaker men, is to our mind a still greater loss, both within and without the University in which he taught, than the loss of what scientific work he might yet have performed.

Dr. Rolleston's personal appearance corresponded with his character. Of commanding height, broad-shouldered, with a head of unusual size, indicating a volume of brain commensurate with his intellectual power, and with strongly-marked and expressive features, in which refinement and vigour were singularly blended, in him we saw just such a man as was described by the public orator at the late Oxford Commemoration, in words with which we may conclude this notice—"Virum excultissimi ingenii, integritatis incorruptissimæ, veritatis amicum, et propugnatorem impavidum." W. H. F.

THE ZOOLOGICAL SOCIETY'S INSECTARIUM

IN our notice of this recent addition to the Regent's Park collection (*antea*, vol. xxiv. p. 38) we regret to find we have made an error in the name of the curator of the Insectarium. Mr. *William* Watkins (not *E.* Watkins as there given) has made many good additions to the collection of living insects under his charge since we last wrote, and attracts a host of visitors every day to inspect his living wonders. In a report on the Insectarium read at a recent scientific meeting of the Zoological Society by the secretary, Mr. Watkins gave the subjoined account of the progress of the development of the large moths of the family Bombycidæ during the month of May.

GLOVER'S SILK-MOTH (*Samia Gloveri*).—Specimens of this species emerged almost daily through the month, and fertile eggs were obtained, which hatched on the 12th instant. The larvæ when hatched are a shining black, with numerous spines of the same colour; after the first change, which took place in six days, they assume a yellowish colour; at the second moult they become green with paler coloured spines, each tipped with bright red. A choice of many shrubs were given them, but although they ate plum and sallow they left these for gooseberry.

CECROPIAN SILK-MOTH (*Samia Cecropia*).—This species emerged through the month, and copulation was frequent. A large number of eggs were obtained, but many are not fertile, perhaps owing to the stock already having been interbred. Young larvæ hatched on the 14th instant, and are growing well. Food-plant, plum.

AILANTHUS SILK-MOTH (*Attacus Cynthia*).—This species commenced to emerge towards the end of the month, but only four specimens have yet appeared. It is usually the latest species of all.

PERNY'S SILK-MOTH (*Attacus Pernyi*).—Perfect insects of this species were on view throughout the month. Fertile eggs were obtained, which commenced to hatch on the 30th instant, and are doing well. Food-plant, oak.

TUSSEH SILK-MOTH (*Attacus mylitta*).—This species commenced to emerge on 28th instant, a beautiful male being bred; on the following day a male and female emerged. Eggs were obtained, which are probably fertile.

GREAT ATLAS MOTH (*Attacus Atlas*).—Throughout the latter half of the month specimens of this species have emerged, and many fine ones have been preserved. Eggs will probably be obtained later; there are many more still to come out.

INDIAN MOON-MOTH (*Actias selene*).—This first specimen of this species emerged on the last day of the month.

AMERICAN MOON-MOTH (*Actias luna*).—During the early part of the month specimens of this species emerged. Eggs have been obtained, but it is doubtful if they are fertilised.

PROMETHEAN SILK-MOTH (*Telea Promethea*).—The cocoons of this species have as yet only produced a large ichneumon fly (*Ophion*). Many visitors have evinced great interest on seeing these large parasites produced from externally perfectly-formed Lepidopterous cocoons and internally stout well-made oval cocoons of the Hymenoptera.

JAPANESE OAK SILK-MOTH (*Antheræa Yama-mai*).—The larvæ of this species produced from eggs have done fairly well; many are now nearly full fed and about to spin. Food-plant, oak.

Besides these fine silk-moths, which are in many cases likely to be of economical value, Mr. Watkins has succeeded in breeding during the past month examples of many of the finer European butterflies, such as the swallow-tail, orange-tip, black-veined white, and *Apatura ilia*, not to mention numerous Heterocera, Hymenoptera, and Neuroptera. During the present month also many additions have been made to the series.

A guide-book to the Insectarium is in preparation, not, as we are assured, with any idea of forcing visitors to buy it, as every object exhibited is fully and perfectly labelled, but rather for the purpose of making the Insectarium better known, and getting further contributions to it from foreign parts.

DR. BESSELS' ACCOUNT OF THE "POLARIS" EXPEDITION[1]

DR. EMIL BESSELS, as most of our readers will remember, was the chief of the scientific department on board the ill-fated *Polaris*, which was sent on her memorable North Pole Expedition by the United States Government in 1871. He finished the text of the present work in the summer of 1874, shortly after the return of the expedition, but postponed the publication until after the appearance of the official account of the voyage, which was edited by Rear-Admiral Davis. He had the misfortune to lose the greater part of his journal and many other papers in his luggage during a railway journey in Scotland.

The remarkable story of the *Polaris* Expedition is well known. Including Captain Hall, the commander of the expedition, the entire number of persons on board the *Polaris* was thirty-three. Of these eight were Esquimaux, consisting of two married couples and their four children, three little girls of ten, eight, and three years of age, and a boy of six. Another boy, who was named Polaris, was born during the voyage in Polaris Bay, on board the vessel. Two of those on board, besides Dr. Bessels, were scientific men, namely, Messrs. R. D. W. Bryan, astronomer, and Friedrich Meyer, meteorologist.

[1] "Die americanische Nordpol Expedition," von Emil Bessels. Leipzig: W. Engelmann, 1879.

The highest point reached by the *Polaris* was lat. 82° 26′ N. at the northern mouth of Robeson Channel. After being beset by ice and having been nipped sufficiently to render her extremely leaky, the ship was moored for the winter about forty miles south of this point in Thank God Harbour, on the east side of Robeson Channel, to the north of Petermann Fjörd. Several sledge expeditions were made from this point, but without reaching a higher latitude than that attained by the ship. Capt. Hall died on board on November 8. In the following summer attempts were made in vain to push further northward, and it was found the ship leaked so badly that it was necessary to return homewards. The ship became beset in the ice on August 16, and remained thus, drifting southwards with the field, suffering constantly from ice-pressure, until October 15, when it was in such jeopardy from the ice-movements that most of the provisions and stores of all kinds and all the boats were passed out on to the ice. The ice parted suddenly, and drifted away from the ship with nineteen persons upon it, including all the Esquimaux, whilst fourteen, and amongst them Dr. Bessels, remained on board. This took place at night. The castaways remained upon the ice 196 days, suffering terrible hardships, and having drifted to the coast of Labrador, were there picked up by a sealing-ship, even the children having survived. They saw the *Polaris* in shore at the commencement of their long journey, and wondered their comrades did not come to their assistance, not knowing that the ship was practically a wreck, and abandoned. Those left on the ship at

FIG. 1.—Walruses at rest on the ice.

the parting of the ice, keeping the leaking ship with difficulty afloat, and unable to see anything of those on the ice, got ashore near Cairn Point in the middle of Smith's Sound, and having wintered there in company with some Esquimaux families, built some boats from the wreck, and travelling south partly in these, partly on the drift-ice, were picked up in the west of Melville Bay by a whaler, the *Ravenscraig*, on June 23. Thus all engaged in the expedition, excepting Capt. Hall, got back in safety.

All this is related by Dr. Bessels in a most graphic and highly interesting style, and his book is filled besides with interesting accounts of the habits of animals met with, the condition of the vegetation of the region explored, the mode of life of the Esquimaux, meteorological and other scientific observations. We shall touch on a few of these. At Fiskernæs, on the south-west Greenland coast, the author turned over some of the kitchen middens of the Esquimaux, such as are now formed in front of each hut. In a very short time remains of all the eatable vertebrates of the Greenland fauna are to be found in them, and in many cases it would not be difficult to fix the season at which the deposits were made, for in places are found scarcely anything but bird-remains, in other places those of fish, in others those of mussels. Many good dogs' skulls and a number of marrow bones of seals broken for their marrow were found in the middens. At the same place one of the sailors of the *Polaris* nearly lost his life by attempting to perform the feat which most of the Esquimaux accomplish with such ease, of turning their kajak upside down without leaving

their seat, and then righting themselves from under water with a blow of their paddle.

Some interesting remarks are made on the calls used by various Esquimaux tribes whilst dog-driving. All the Esquimaux of that part of Greenland, which is under missionary influence, drive their dogs with the call *i! i! i!* and accompany the sound with a smack of the whip to the right or left when they wish to turn, whilst the dogs are

FIG. 2.—Littleton Island.

stopped by a short whistle. The Esquimaux tribe on the side of Smith Sound use similarly the sound hă! hă! hă! and as a halting signal a lengthened ōh! Those inhabiting the neighbourhood of Ponds Bay, as one of the Esquimaux on board the ship informed the author, use the call wōă-ăh-hă-hă-hă! to turn their dogs to the

FIG. 3.—Group of Ita Esquimaux huts with *Polaris* House and the wreck in the distance.

right, and ăh-wōă-wă-hă! to send them to the left; ōh! for halt. The calls used in Cumberland, a district of Baffin's Land, are somewhat similar sounds to the last; formerly they were more like them still, but have changed. The natives on the shores of the Hudson's Straits use only the call au! au! au! and those of King

William's Land only kgu! kgu! kgu! Amongst these two latter tribes the whip is almost unknown; the dogs are led or turned from side to side by means of a piece of wood which the driver throws out on the side from which they are to turn. The Esquimaux of Alaska appear to have no stereotyped driving cries, but merely to use various oaths promiscuously as they come to mouth.

During one of the author's sledge expeditions, where the going was very bad in consequence of the yielding of the snow, the dogs could hardly be got along with the whip, so two Esquimaux who accompanied him took turns to run in front of the team, trailing a fish tied to a string. The dogs struggled to get at the herring, always out of their reach, and excellent progress was made.

Some interesting details concerning the habits of Esquimaux dogs are given by the author. The instant halt is called by the driver the dogs throw themselves to the ground with their snouts between their forepaws; they rise again to stretch, and then lie down again at once. Two Newfoundland dogs which belonged to the *Polaris* pack gradually assumed similar habits; but before lying down they always turned round and round in their resting-place, like all dogs except the Esquimaux breed, for the author never saw an Esquimaux dog do this. Mr. Darwin, as will be remembered, has explained this habit of turning round before lying down, invariably to be observed in other domestic dogs, as a survival of the instinct of the wild ancestor, which leads him to form a bed in the grass by this means. Every one has heard of the extraordinary voracity of the Esquimaux dogs; they will even sometimes snap off a piece of their master's flesh if carelessly exposed. One day, on board the *Polaris*, the porcelain door-handle of one of the cabins fell off with the usual square rod of iron attached to it. Five or six of the dogs made a rush at it, there was a momentary struggle, the dogs were hastily driven away, but the door knob was already swallowed. The dog that ate it was none the worse, nor the handle either in the end. An Esquimaux told the author that the following were the points to be noticed in selecting a good dog:—a broad breast, short ears, strong legs, large feet, low loins, and a moderately long tail. The tail must not bend too near its root, as this shows the loins to be weak.

The descriptions of the Esquimaux and their habits throughout the work are worth reading. The most interesting are those relating to the Ita Esquimaux, inhabiting the north shore of the Foulke Fjörd, with whom the author and his companions spent their second winter. They consisted of nine men, three women, and eight children, who crowded at night the small house built by the shipwrecked party, and as there was no room for them usually to lie down, slept sitting with their backs against the walls. The floor measured only twenty-two feet by six, yet had to accommodate thirty-four persons, and once thirty-eight. It was no use erecting a tent for the visitors under the lee of the house; they preferred the close quarters inside.

The author's principal friend was Awatok, the priest of the tribe. He usually accompanied him when it was his watch, on his hourly rounds to the meteorological instruments. "We walked generally arm-in-arm, and when there was no snow drifting sang the tune of the spirited student's song, 'Was kommt dort von der Höh',' using bum—bum—bum instead of the words. After a little while he learnt to hum the tune fairly well." After some time the natives built snow huts near the *Polaris* house, and settled for the winter. The first to do this was one named Stokirssuk, but called "Jimmy" by the *Polaris* people. He was born near Cape Searle, about 650 miles south of Port Foulke. Whilst he was a youth he and his father left their home and wandered north and reached Cape Isabella, where they fell in with an Esquimaux tribe, of whose existence they had been ignorant. Here Jimmy married a wife with tattooed face, and five summers before the arrival of the *Polaris* had moved up thence to Ita, in a company consisting of a woman's boat and four kajaks. He had forgotten how many persons composed the expedition. They found Capt. Hayes' lifeboat on Littelton Island and destroyed it, and discovering the observatory at Port Foulke which Hayes had left filled with provisions and other things, lighted a fire there to cook birds. Unfortunately close to the fireplace was a canister full of powder; the observatory was blown up, and several persons killed and wounded. Jimmy related, his face beaming with laughter, how his father-in-law was killed, and indicated with a movement of his hand how the old fellow was shot up into the air. A dog which had accompanied Jimmy during all his wanderings was still fresh and strong.

Another noticeable native of the band was Majuk Kane's former companion; he was always hungry and a beggar. He named his youngest son, scarcely six weeks old, Dâkta-kè, which meant no more or less than Doctor Kane. This he did in order to flatter the *Polaris* people and ingratiate himself. Sometimes he brought a walrus liver or a few tongues, and got bread or tinned meat for them, at others a skin to get a harpoon for it. But in some moment, when unwatched, he would eat the tongues himself and carry off the liver again; but he did it so innocently that it was impossible to be angry with him. At one time during the winter the Esquimaux were nearly starving, yet one of them—Awatok—would not beg for his family, and when a present was at last sent to him of bread and bacon, had already killed five of his dogs to keep his wife and children alive. His strength of character and power of self-denial were remarkable.

The Ita people have no boats, and do not possess the bow and arrow, although words for these things still exist in their language. These facts show a very remarkable degradation, especially in a hunting people. Jimmy alone had a bow and three arrows. They had often been mended, and being very seldom used, were in a wretched condition, and Jimmy himself was a very bad shot.

One burial took place during the stay of the author. The corpse was wrapped in skins placed on a sledge, and buried in the snow with the face turned westwards. After the body was covered the sledge was turned over on top of it, and the hunting implements of the deceased laid by it. The men plugged their right nostril with hay, and the women their left, and these plugs were worn for several days, and only taken out when the wearers entered a hut. When it is possible a heap of stones is usually raised over the corpse. The nineteenth chapter is devoted to an ethnological sketch, in which the culture and characteristics of the various Esquimaux tribes are compared.

A good many musk-oxen were met with, and the author gives a valuable account of the habits of this animal. None of those killed by the *Polaris* people had a very marked musk smell. The author is uncertain whether this peculiarity is to be attributed to the very high latitude in which they were obtained, or to their having been killed out of the breeding season. No difficulty was found in distinguishing the tracks of these animals from those of reindeer, although some former observers have not found this easy. In all the herds there are from ten to twenty cows to one bull. Their voice is somewhat like the snorting of the walrus, and never resembles in the least the cry of the goat or the sheep. When danger approaches they never give signal with their voice, but only by stamping or striking their neighbour with their horns. They have dire combats with bears sometimes, and often come off victors.

A report, as will be remembered, was spread by newspapers at the time of the return of the expedition, that the *Polaris* had discovered walnut driftwood in the high north, and gave the author as an authority for the statement. Nothing however but coniferous wood was in reality

found. One of the most important matters contained in the book is the author's account of a Bathybius-like albuminous substance which he discovered in the mud composing the sea-bottom, at a depth of ninety or ninety-five fathoms north of Smith Sound. The specimens of mud were brought up in a water-bottle apparatus, about a large spoonful being obtained each time of sounding. This mud was very sticky, and showed itself under the microscope to consist of a yellowish gray mass with numerous opaque lime particles embedded in it. If some of the mud was left to rest in a hollowed out glass slip for some time the albuminous masses exhibited unmistakable amœboid movements, and took into their substance particles of larmine. The substance is named *Protobathybius*.

We cannot follow the author further. His book is well worth reading, and only escaped notice here sooner through accident. It is well illustrated throughout. He takes exception on the ground of priority to the name Palæocrystic Sea, which Sir George Nares conferred upon the expanse which the Americans had previously named Lincoln Sea. He states that, owing to the neglect of his work by an assistant, numerous serious errors occur in the official volume of scientific results of the *Polaris* expedition already published, especially in the meteorological department. These are corrected in the appendix to the present volume, which contains also much other scientific matter. He finds fault throughout his book with the conduct of the ice-master of the *Polaris*, S. O. Buddington, and considers that the ship might have reached higher latitudes if, on two occasions which he believes were favourable, a push had been made northward. He accuses Buddington of not even going up into the crow's-nest as often as he should have done to examine the state of the ice. Some official correspondence which passed on board the ship on these questions of the management of the expedition is given in the book. The manner in which the meteorological observations were kept up after the shipwreck, and the devotion with which Dr. Bessels attempted, though in vain, to sledge far north after the wreck from *Polaris* house are highly creditable.

The book is dedicated to the Arctic explorer, Capt. A. H. Markham, R.N., who with great kindness, and at very considerable inconvenience, shared his cabin on board the whaler *Arctic* with Dr. Bessels on the voyage to Dundee, the *Ravenscraig* having fallen in with the *Arctic* on the whaling-grounds. H. N. MOSELEY

THE COMET

THE comet which, so far as we are yet informed, was first astronomically observed in the southern hemisphere on May 29, is now well under observation in these latitudes, and as its position will become more and more favourable, it will be a mere question as to how long our telescopes will show it, what data may be obtained for an accurate determination of its orbit. The elements appear to have some resemblance to those of the great comet of 1807, to which reference was made in Dr. Gould's early telegram from the observatory at Cordoba, but the identity of the comets appears highly improbable after Bessel's classical memoir containing a rigorous investigation of the orbit of the comet of 1807, which he followed until the perturbations of the known planets had ceased to be sensible. We may briefly recall the circumstances attending the appearance of that body and one or two main results of Bessel's investigation. According to Piazzi it was first detected by an Augustine monk at Castro Giovanni in Sicily on September 9, but the first regular observation was made on the 22nd of the same month by Thulis at Marseilles. From this time the comet's positions were determined at every opportunity by Bessel, Olbers, Oriani, and others until the end of February, 1808, and on the 18th of the following month Wisniewsky, favoured by a very acute vision and the clear skies of St. Petersburg, observed the comet again, and succeeded in fixing its position until the 27th. In consequence of a notification from Olbers, that with powerful telescopes there might be a possibility of observing the comet again as the earth overtook it to some extent in October and November of the same year, Bessel, then working with Schroeter at Lilienthal, closely examined its track with reflectors of 15 and 20 feet focal length, and on November 9 did succeed in finding an extremely faint nebulosity near the computed place of the comet, which he could not find subsequently, but as the position differed 12′ from that assigned by an orbit which he considered very exact, he came to the conclusion that the object he observed was not the comet of 1807, but another one which happened to be in the vicinity, and which was not seen elsewhere. The discussion of the six months' observations of the comet appears in the masterly treatise to which we have referred, viz., "Untersuchungen über die scheinbare und wahre Bahn des im Jahre 1807 erschienen grossen Kometen," published at Königsberg in 1810. The method of determining the perturbations of a comet due to planetary attraction, which is detailed in this memoir, was long practised by the German astronomers in similar cases.

Bessel inferred from his researches that at the perihelion passage of the comet on September 22 it was moving in an ellipse, with a period of revolution of 1714 years, which was reduced to 1685 years at the date of Wisniewsky's last observation, and continuing his computation of the perturbations to March, 1815, when the effect of planetary attraction had become very small, he found the period further reduced to 1543 years.

The general aspect of the comet now visible as viewed in an excellent *Cometen-sucher*, reminds us of the appearance of the comet of June, 1845, discovered by Colla, which was observed under very similar circumstances, and it may be mentioned that Encke stated at the time that the comet of 1845 reminded him strongly of the great comet of 1819, which passed across the sun's disk on June 26.

The present comet appears to have been at its least distance from the earth about June 21, and should soon present a material diminution of brightness. In perigee its distance would be about 0·3.

[Since the above was in type we have received observations from Dr. Elkin, of the Royal Observatory, Cape of Good Hope: After a week of overcast sky the comet was found there on May 31. Mr. L. A. Eddie, F.R.A.S., of Graham's Town, saw it on May 27, and others claim to have seen it two days earlier. On June 4 the tail was 6° long, coma 20 minutes, and nucleus 20 seconds in diameter; the comet was as bright as *a* Columbæ.]

The following opinions of American astronomers have appeared in the *Daily News*. That paper, with wonderful journalistic enterprise, has not hesitated to telegraph nearly a column of matter from America on this subject:—

"Prof. Stone, of the Cincinnati Observatory, thinks it is not the comet of 1812, because of its not moving in a southerly direction, but that it may possibly be that of 1807. Professors Eastman and Skinner, at the Naval Observatory, succeeded in getting some fair observations of the comet on Friday night, although the night was not altogether favourable. Prof. Skinner describes the comet as having an extremely bright nucleus, which presented a very ruddy appearance. The observers did not know whether this appearance was normal, or was due to the prevailing atmospheric conditions. Prof. Skinner estimates the tail, which is fan-shaped, at about eight degrees in length. It was also ascertained that in twenty-two minutes the comet travelled three seconds in arc, and in an hour nine seconds, giving it a daily rate of travel northward of about three degrees thirty-six seconds. Computing its motion from its position when discovered,

Prof. Skinner found that in two days and a quarter the comet moved about ten degrees. On Saturday morning it became distinctly visible at 1·45, and could be seen until the sun rendered invisible all the stars except Venus. The astronomers at the observatory maintain their opinion that this comet is identical with the one recently observed by Dr. Gould in Buenos Ayres. Prof. Skinner describes it as a much finer comet than Coggia's, which appeared in 1874, and brighter than any since that which appeared in 1843.

"Prof. Newcomb said that as all the observations made on the comet of 1807 showed it to have a period of nearly 1700 years, it seems out of the question that under any circumstances the same comet could have returned in so short a time as seventy-four years, unless it has passed in the vicinity of some larger planets, which it could not have done. From Dr. Gould's telegram it may be inferred that the comet was very near the orbit of that of 1807 when he observed it. Prof. Newcomb is inclined to think that it is a case of two comets moving in nearly the same orbit, rather than the return of the same comet. One reason for this is that if it had been a periodical comet returning every seventy-four years, it could not have failed to have been observed on former occasions, because it would have returned in 1734 and in 1760. In neither of these years was any such comet observed. The position of its orbit is such that it could hardly have failed to be seen had it returned. Prof. Henry Draper has photographed the comet. To obtain such a photograph as he would like, he said, the plate ought to be exposed for at least an hour, but he had succeeded in getting an exposure of only seventeen minutes. The result, however, was satisfactory, in so far that it demonstrated the possibilities of photographing a comet. It showed the nucleus and the coma and part of the tail. He will try again to obtain a longer exposure. He wishes to take a larger photograph if possible, to examine more carefully the structure of the tail; but the larger the photograph, the more difficult it is to obtain, owing to the diffusion of the light. If he succeeds in obtaining two good photographs he will next turn his attention to its spectrum, which is much more difficult to photograph than the orb itself.

"Prof. Bois, of Dudley Observatory, at Allebuy, secured a number of valuable observations. He says that at two o'clock on Saturday morning its appearance both to the naked eye and in a telescope was magnificent. The head of the comet was very bright, and the tail thirty or forty minutes broad, extending nearly 20° toward the North Star. The tail was very diffused and nebulous, spread out in fan-like form. Looking in the great telescope of thirteen inches aperture, a multitude of details became revealed which are not visible to the naked eye. The head was there seen to consist of a condensed nucleus, apparently about as large as Jupiter seen in a telescope, but of far greater intensity of light. A spray of brilliant rays spread out from the nucleus on the side nearest the sun, then, turning backward, mingled with the elements which form the tail. This resembled the jet of a fountain very closely in its general features. The tail itself extended in a direction diametrically opposite the sun. The whole field of the telescope was filled with glowing nebulosity. I am inclined to think that this comet has not been seen before this year, in modern times at least. It is probably the same comet as seen in South America. It is now certain that this is not the long-expected comet of 1882. It is almost equally certain that it is not the comet of 1807. The period of the comet of 1807 is about 1,700 years. Prof. Swift of Rochester says the comet grows smaller and brighter in nucleus, showing that it is approaching the sun. The head is active, and the tail does not obscure the stars. He thinks it will be visible several weeks. He cannot yet determine if the comet was ever before seen. Great activity is apparent in its head."

M. Janssen has presented to the Academy of Sciences, at its sitting of June 27, the *cliché* of a photogram of the comet, which was taken with the large telescope he described a few weeks ago, constructed for the purpose of astral photography. He obtained also a series of photograms of the nucleus, for which he varied the time of exposure. The results prove that the brightness is not more than that of a star of the fifth magnitude. On the photograph, which will be printed in NATURE, and which our correspondent has examined, the stars are visible through the tail. M. Faye delivered a speech praising the success realised by his colleague, and remarking that it was the first time that a comet had been photographed. The opinion that the tails of comets are merely an illusion, as professed by Seneca in his "Quæstiones Naturales," seems to gain ground, owing to the extraordinary transparency of these appendages.

WE have received the following communications :—

THE following positions which I obtained of the path of the comet may interest your readers :—I saw it first on Wednesday, June 22, at 10.55, during a break in the clouds for about a minute. It was then brighter than it was last night, the 27th, when I saw it well, the sky being clear. The colour is of an orange tinge, and the tail extends to about 10°, but can only be seen so far by sweeping across it. It has changed wonderfully since I first observed it, as will be seen by the drawings which I send you. The No. 1 Drawing shows a most singular appendage round the nucleus, in shape like a milkmaid's yoke, the nucleus occupying the hollow, which was black. From the nucleus two horns projected; they were as bright as the nucleus.

FIG. 1.

The first envelope on the preceding side took a sudden bend from the circular form to a straight line, while the outer envelope retained its parabolic form.

Last night, the 27th, I was surprised to find a great change had taken place the yoke-shaped central luminosity appeared as if it had turned round in the nucleus

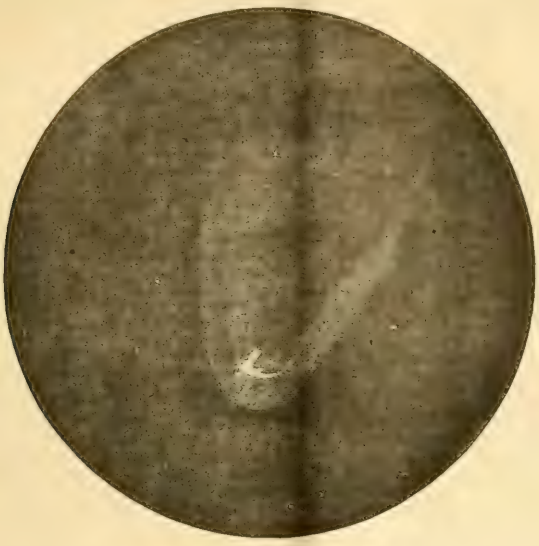

FIG. 2.

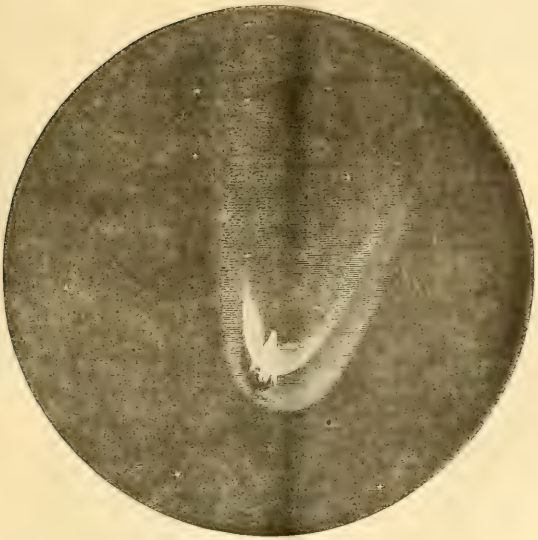

FIG. 3.

and occupied the usual position, while the nucleus itself had thrown out a bright tail, which gave it the appearance of a small comet lying across the bright envelope (Figs. 2, 3). The outer envelope on the following side was interrupted in its continuity, or seemed wanting.

The positions I got are as follows:—

		h. m.		R.A. h. m. s.		N.P.D. °
June 23	...	11 0	...	5 33 59	...	44 55
25	...	10 0	...	5 41 41	...	36 52

27	...	12 0	...	5 55 54	...	29 42

so that last night it crossed the path of Brorsen's comet of April 30, 1879. R. S. NEWALL

Ferndene, June 28

Photographic Spectrum of Comet

On Friday night (June 24) I obtained, with one hour's exposure, a photograph on a gelatine plate of the more refrangible part of the spectrum of the comet which is now visible. This photograph shows a pair of bright lines a little way beyond H in the ultra-violet region, which appear to belong to the spectrum of carbon (in some form) which I observed in the visible region of the spectra of telescopic comets in 1866 and 1868. There is also in the photograph a continuous spectrum in which the Fraunhofer lines can be seen. These show that this part of the comet's light was reflected solar light.

This photographic evidence supports the results I obtained in 1868, showing that comets shine partly by reflected solar light, and partly by their own light, the spectrum of which indicates the presence in the comet of carbon, possibly in combination with hydrogen.

Upper Tulse Hill, June 27 WILLIAM HUGGINS

COMET 1881 *b* was well observed at the Royal Observatory, Greenwich, on June 24 and 25. Its position was determined on both evenings with the altazimuth and transit-circle. The following are the places deduced from the meridian observations (uncorrected for parallax and aberration) :—

	G.M.T. h. m. s.	R.A. h. m. s.	N.P.D. ° ′ ″
1881 June 24 ...	11 25 40 ...	5 38 38·94 ...	40 36 39
25 ...	11 25 55 ...	5 42 51·06 ...	36 39 30

The observation on June 25 indicates the following corrections to the ephemeris computed by Mr. Lohse from the elements communicated by the Emperor of Brazil (Dunecht Circular, No. 21) :—Correction in R.A. + 9m., in Dec. + 6° 23′. On June 24 the head was estimated to be brighter than Vega or Arcturus, notwithstanding its low altitude, and on June 25 it appeared decidedly brighter than Arcturus, the star being at about 10° greater altitude than the comet. The tail, which was slightly curved (convex towards the preceding side), was traced to a distance of about 8° on June 24, and 10° or more on June 25, its general direction pointing to the star 2 Ursæ Minoris, about 3° east of Polaris. With the Sheepshanks equatorial (6¾ inches aperture) the head showed the want of symmetry that has been remarked in some other comets. On June 24 the preceding side was much the brighter, there being a strong brush or arc of light on that side, with a bright fan close to the nucleus and a much smaller arc on the following side, the two arcs appearing to spring from the nucleus on opposite sides, and higher up to interlace. A very remarkable feature was a straight wisp of light extending from the nucleus nearly along the axis of the tail. On June 25 this had become much less striking, and the appearance of the head had entirely changed. The following side was then much the brighter, and the general appearance was that of a parabolic envelope, with a much brighter unsymmetrical parabola placed within it, the latter having its focus on the following side of the nucleus, and its axis turned round in the direction *n p s f* from that of the tail.

The greater part of the head gave a bright continuous spectrum, obliterating the usual cometary bands, but one portion showed three bands, in the green, blue, and violet respectively. Measures of the principal band in the green showed that it coincides with the band in the first spectrum of carbon (blue base of flame) at 5165, and not with that of the second spectrum (vacuum-tube) at 5198. The bands in the blue and violet appeared to correspond, as nearly as could be estimated, with bands in the first spectrum of carbon. These observations were made with the half-prism spectroscope mounted on the 12¾-inch equatorial, a dispersive power of about 18½° from A to H being used, with a magnifying power of 14 on the view-telescope, as in the measures of star-motions in the line of sight. No decided polarisation was detected either in the head or the tail. Cloudy weather has prevented any observation of the comet since June 25.

W. H. M. CHRISTIE

Royal Observatory, Greenwich, June 28

IN a letter to the *Times* of the 25th inst., Mr. Ranyard says of Comet *b* 1881, at present visible in the northern heavens :—"In general brightness it decidedly outshone the star Capella. . . . With a direct-vision spectroscope of five prisms, and a 3½-inch telescope, its nucleus and head gave a continuous spectrum, on which I could not detect any bright bands." Last night, June 27, shortly before midnight, the brilliancy of the nucleus had considerably decreased, and yet with a five-prism direct-vision spectroscope I could see most clearly, along with the continuous spectrum, three green bands, not only in the nucleus, but also in the surrounding coma. Two of the bright lines were still strong in the neighbourhood of the nucleus, even where the continuous spectrum was very faint. I used an ordinary Browning spectroscope on an 8-inch achromatic. A small McClean's spectroscope gave only the continuous spectrum, as seen by Mr. Ranyard. This was, I think, due merely to the brightness of the continuous spectrum ; for in the Browning instrument the bright lines over the continuous spectrum were not very conspicuous with a wide slit, but on narrowing the slit the green bands became much brighter than the rest of the spectrum.

On June 25 the night was rather cloudy, but good observations for position were obtained by observing the transit of the comet and of δ Aurigæ over the wires of an eyepiece of the equatorial. The mean of four wires gave R.A. 5h. 42m. 51·34s., at G.M.T. 12h. 11m., the North Declination being 53° 30′ 57″·6.

On June 27, towards midnight, the double envelope surrounding the nucleus was clearly defined in the telescope, as was also the bright bundle of rays, which spread out in the direction of the sun and extended to a point in the coma about half way between the bounding lines of the inner and the outer envelopes. The direction of these bright rays, which were very vivid, was not quite opposite the direction of the tail, and the latter was very slightly curved.

A transit of the comet, *sub Polo*, was observed last night, June 27, at G.M.T. 11h. 38m., and this, combined with the corrected reading of the meridian circle, gives the following position :—R.A. 5h. 52m. 46·31s., North Declination 60° 13′ 40″·6. The length of the tail, clearly discernible to the naked eye, was last night about 9°.

S. J. PERRY

Stonyhurst Observatory, Whalley, June 28

THE following places have been obtained with the transit-circle when the comet passed *sub Polo* :—

Remarks.—(*a*) The nucleus distinct but nebulous. Tail bright, and estimated 15° in length. Observation good.

(*b*) Observation difficult, owing to cloud.

(*c*) Nucleus better defined than on June 23, but not so bright. Length of tail estimated at 15°. Observation good.

(*d*) Observation fair, very cloudy. Tail 12°-15° in length

Radcliffe Observatory, Oxford E. J. STONE

THE comet was examined spectroscopically here last night at 11·30. The nucleus gave a bright continuous spectrum, while the coma and brighter portions of the tail gave the three least refrangible hydrocarbon bands superposed on a faint continuous spectrum. On moving the slit of the spectroscope towards the fainter part of the tail the bands died out, leaving a faint continuous spectrum, which again gradually faded away as the end of the tail was approached. I have not measured the position of the bands, but they are sensibly the same as those from an alcohol flame. GEORGE M. SEABROOKE

Temple Observatory, Rugby, June 28

NOTES

THE Lords of the Committee of Council on Education, in reply to an application for aid to science teachers attending the classes of the Mason Science College two days a week, agree to pay three-fourths of the fees for the chemical and physical laboratories and for biology and histology, for a limited number of teachers, on condition that satisfactory terminal reports of their progress (ascertained by examination) and of their conduct be received at the end of the Michaelmas, Lent, and Easter terms. Applications for the privilege must be made to the Secretary, Science and Art Department, not later than August 31. The selection will rest with that Department. One-fourth of the fee for the whole session must be paid by the student on entrance; and the remaining three-fourths will be paid by the Department in equal instalments at the commencement of each term, if the reports are satisfactory.

THE fine library of the late M. Chasles is to be sold by public auction between June 28 and July 18. It contains no fewer than 3936 works, or about 15,000 volumes, and is one of the most complete libraries of mathematical works in existence. The precious manuscripts and various works of history and philology will doubtless be eagerly sought by amateurs. There is, among other works, a Geography of Ptolemy of Alexandria, printed at Rome in 1490, containing geographical maps which are the first engraved with copper plate (1478). The collection includes eighteen different editions of Archimedes, and the works on Euclid number sixty-six. The astronomical works of the sixteenth, seventeenth, and eighteenth centuries are fully represented, as also those on astrology, alchemy, &c.

THE programme of an excursion by the Geologists' Association to the Lake District, from Monday, July 18, to Saturday, July 23, has been issued. Keswick will be the centre of operations till Friday, when the Grasmere and Ambleside district will be visited. Saturday will be given to Windermere.

WE have also before us an attractive programme of a marine excursion to Oban and the West Highlands of Scotland by the Birmingham Natural History and Microscopical Society. The party leave Birmingham on the evening of July 1, and go direct by Greenock and the Kyles of Bute to Oban, which is made the centre for various excursions by sea or land, till July 12. Facilities for dredging will be afforded. The party will include some able naturalists.

IN a recent issue we gave some account of the Ben Nevis Observatory (so-called). The system has been in operation since June 1, and the daily observations by Mr. Wragge are published in the *Times*. This gentleman begins his magnanimous toil up the hill every morning at 5 o'clock. After spending about an hour on the top (9 to 10) in taking observations with the scanty stock of instruments fixed on stands protected by a stone screen, he gets home again by about 2 in the afternoon. In the early part of June the path up the mountain was often deep in snow and enveloped in mist, but Mr. Wragge has marked out the track with a succession of cairns. Anything more disgraceful to British science than this state of things, as representing our present achievement in the way of regular mountain-observations, it is difficult to conceive! A comparison with what has been accomplished in other countries, notably America, where well-equipped observatories are now to be found at vastly greater heights than the top of Ben Nevis, is sufficiently humiliating for us.

THE May number of *Naturen* gives the first of a series of papers, by Prof. Axel Blytt, on "the "Theory of the Immigration of the Norwegian Flora at Different Earlier Geological Periods." In this paper the author, who is well known as the highest authority among Scandinavian botanists, describes the character of the flora, which, considered generally, is represented by only a small number of genera. At an elevation of 4000-4500 feet above the level of the sea the interior and southern districts exhibit dwarf forms of the willow and birch, with juniper; between 3000-3500 feet the first birch woods appear in the same districts, while firs and pines begin a few hundred feet lower. Here and there the high and barren fjalds of the interior near the glaciers are broken by the occurrence of blooming oases of plants of Arctic continental forms, which, after having lain buried for months under the snow, awaken to new life with the return of the summer sun. To the interior also belongs a boreal flora of small deciduous trees, including the oak, ash, alder, lime, &c., which penetrate as far as 2000 feet, and in the Inner Sogn district occur the only woods of elm and wild cherry to be found in Norway. The subboreal belt, including several Spiræas, *Fragaria collina*, *Artemidia campestris*, *Thymus chamadrys*, &c., is limited to the Lower Silurian formations in the eastern districts. The western coast-lands between Stavanger and Christiansund are the habitats of an Atlantic flora, including *Erica tetralix*, and several of the rarest Norwegian plants, but here Calluna, Sphagna, and Carices, with turf beds, constitute the principal forms. The most southern littoral belt near Christiansund presents a sub-Atlantic flora, while a number of sub-Arctic forms appear scattered over the whole of Norway. Prof. Blytt considers that the sporadic occurrence of the various continental and insular forms of the flora of Norway points to the conclusion that the climate has undergone various secular changes since the Glacial period, the continental forms having immigrated during the continuance of drought, when the peninsula was connected with neighbouring continents, while the appearance of the insular forms was contemporaneous with rainy periods.

THE decree appointing sixty-five French members of the Congrès d'Électricité has been signed by the President of the Republic, and will soon be published. Foreign Governments will appoint all their own members. Reporters and the public will not be admitted to the Congress; an official report will be published by the general Committee. Some French papers have already condemned such practice in strong terms. No jurymen will be appointed by the exhibitors, and the latter will have no direct influence on the verdicts. It is proposed to consult the Congress on certain measures of general interest, *e.g.* the adoption of electrical units. The electric railway station will be placed inside the building. For want of time, no viaduct will be constructed, and the rails will be laid on the common roads. The space allotted to English exhibitors on the ground-floor has been largely occupied. In addition to this space each of the British light exhibitors will have on the upper floor a special saloon to illuminate with his own system. The right of publishing and selling the French Catalogue has been purchased by the printers and publishers of *La Nature*, rue de Fleurus. The sale of scientific papers will be authorised, but will take place exclusively through their agency.

IN an old book—"Thomæ Bartolini Acta Media et Philosophica Hafniensa Anno 1674, 1675, et 1676," Herr Budde has

come upon a passage which bears on the history of the diving-bell. Bartolini there writes: "Singulare instrumentum invenit descripsitque Franziscus Kesler Wetzlariensis in secretis suis Oppenheimii editis 1616, capite VI., quod Wasserharnisch vocat, quo tuto ambulemus in fundo maris, legamus ibidem, scribamus, edamus, potemus, cantemus, sine periculo vitæ longiori tempore, omnia pergamus, thesauros eruamus et abscondamus," and so on. Of the two figures one represents the interior—a rough frame-work of wood, having straps with which the diver secures himself in the bell; the other (see *Wied. Ann.*, No. 5) shows the exterior, an inverted vessel of tumbler shape having five or six small circular windows at the top, while the man's legs project little below. According to Poggendorff (it is stated) the oldest book in which the diving-bell is mentioned is of 1664, and it refers to a work of Taisnier (as the source of information), the date of which Poggendorff does not give.

We learn from *L'Électricité* that there is being made near the Palais de l'Industrie a basin, 16 metres in diameter, which will be put at M. Trouvé's disposal for exhibition of his boat driven by electricity. In the centre will be an electric light on a pedestal. At various points within the Palais de l'Industrie will be placed (under the direction of MM. Ranvier, Berger, and Fontaine) models of statues as supports for the electric light in its various forms.

The Municipal Council of Philadelphia has granted to a Company the right to place 3000 kilometres of wire on posts for telephonic purposes. No tax is imposed, but a limit is set to the subscription. The fire-telephones in Berlin have proved so useful, that the municipal authorities are increasing the number. In Paris the development of telephonic lines amounted to 9121 kilometres, the extent of wire being double this.

An electromagnet of enormous dimensions has lately been made by Herren von Feilitzsch and Holtz for the University of Greifswald. The case is formed of twenty-eight iron plates bent into horseshoe shape, and connected by iron rings so as to form a cylinder 195 mm. in diameter. The height is 125 ctm.; the total weight 628 kilogr. The magnetising helix consists of insulated copper plates and wires having a total weight of 275 kilogr. (For further details see *Les Mondes* of June 23.) With fifty small Grove elements the magnet will fuse in two minutes 40 grammes of Wood's metal in the Foucault experiment. The plane of polarisation is rotated in flint glass after a single passage, &c. The core of the largest magnet hitherto known, that of Plücker, weighed 84 kilogr. and the wire 35 kilogr.

Mr. W. Mattieu Williams, F.R.A.S., F.C.S., author of "The Fuel of the Sun," "Through Norway with a Knapsack," &c., has been appointed to the management of the Royal Polytechnic Institution, Limited, and will commence his duties at once.

Mr. H. C. Russell, Government astronomer, has just sent home his report on the results of rain and river observations made in New South Wales during 1880. In regard to the latter part of the subject Mr. Russell remarks that it seems impossible to doubt that an unlimited supply of water passes away underground, more indeed than would suffice to make the western districts of the colony a well-watered country, and all that is wanted to make the supply available is a judicious use of the boring-rod. The report is illustrated by an interesting rainfall map of New South Wales, and another on which are given curves showing the height of the western rivers during the year.

Four shocks of earthquake occurred at Agram on the night of June 22-23; rather severe shocks were felt on June 22 at Bobyhad (10.20 p.m.) and Szegszard (11 p.m.) in Hungary.

A skeleton of an *Ursus spelæus* was found this week in a cave near Spanheim (Germany).

The arrangements for the International Medical and Sanitary Exhibition are now complete; the offices are removed from the Parkes Museum to the Exhibition Buildings at South Kensington. The Right Hon. Earl Spencer, Lord President of the Council, has accepted the office of president, and will be present at the opening ceremony on Saturday July 16. The Exhibition is to be complete on Wednesday, July 13, and the judges will make their examinations for the awards on the two days previous to the opening.

In consequence of the increasingly numerous cases of myopia developed in French schools through bad arrangement of seats and distribution of light, the Minister of Public Instruction has nominated a commission named De l'Hygiène de la Vue dans les Ecoles, whose object will be to study the influence of the material conditions of school arrangement on the progress of myopia, and to discover the means of counteracting the evil.

A careful study of the chief methods in use for the chemical examination of potable water, so far as organic matter is concerned, has been undertaken by order of the U.S. National Board of Health. Medical men throughout the country, and others interested in sanitary matters, have been requested to report to Dr. Mallet of Virginia University any well-marked case of disease from impurities in drinking-water, and to forward samples of such water.

The additions to the Zoological Society's Gardens during the past week include two Red-handed Tamarins (*Midas rufimanus*) from Demerara, presented by Mr. John Pe-quë; a Stanley Crane (*Tetrapteryx paradisea*) from South Africa, a Common Chameleon (*Chamæleon vulgaris*) from North Africa, presented by Mr. J. Sexton; two Laughing Kingfishers (*Dacelo gigantea*) from Australia, presented by Sir Hubert Sandford; a Lead-beater's Cockatoo (*Cacatua leadbeateri*) from Australia, presented by Mr. Martin Smith; a Marsh Harrier (*Circus æruginosus*) from Malta, presented by Mr. J. Wolfe Murray; a Lesser Kestrel (*Tinnunculus cenchris*), South European, presented by Mr. William Brodrick; an Undulated Grass Parrakeet (*Melopsittacus undulatus*) from Australia, presented by the Countess of Ellesmere; two Gerbillus (*Gerbillus*, sp. inc.) from Algeria, presented by M. Alphonse Milne-Edwards; a Long-headed Snake (*Xenedon rhabdocephalus*), a d'Orbigny's Snake (*Heterodon d'Orbignyi*) from South America, presented by Dr. A. Stradling, C.M.Z.S.; a Red-throated Amazon (*Chrysotis collaria*) from South America, deposited; three Moustache Monkeys (*Cercopithecus cephus*), a Diana Monkey (*Cercopithecus diana*), a Talapoin Monkey (*Cercopithecus talapoin*), two Green Monkeys (*Cercopithecus callitrichus*), a White-collared Mangabey (*Cercocebus collaris*), a Grey-cheeked Monkey (*Cercocebus albigena*), two Water Chevrotains (*Hyomoschus aquaticus*), a Crested Guinea Fowl (*Numida cristata*) from West Africa, a Tamandua Anteater (*Tamandua tetradactyla*), a Peba Armadillo (*Tatusia peba*), a Red-billed Toucan (*Ramphastos erythorhynchus*) from Brazil; a Hawk's-billed Turtle (*Chelone imbricata*) from the East Indies, a Puff Adder (*Viper arietans*) from Africa, purchased; a Horned Tragopan (*Ceriornis satyra*), an Impeyan Pheasant (*Lophophorus impeyanus*), bred in the Gardens.

BIOLOGICAL NOTES

Rhythmic Contraction of Voluntary Muscles.—It has been recently observed by Herr W. Biedermann (Vienna Acad. *Sitzungsberichte*) that if the sartorius muscle of a curare-poisoned frog, prepared at a low temperature, be put in a solution of 5 gr. NaCl, 2 gr. Na_2HPO_4, and 0·4 to 0·5 gr. $NaCO_3$ in 1 litre water, it shows, after a longer or shorter time of rest, *rhythmic* contractions, which continue regular a certain time for each part of the immersed muscle. Then occur periods of rhythmic contractions, separated by longer or shorter pauses, and often varying in character. These phenomena last a long time; with a con-

external temperature for days. The author saw preparations still pulsating strongly and regularly on the fourth day. (The liquid, in that case, must be often renewed.) These rhythmic contractions of a voluntary striped muscle, indicating chemical stimulus, awaken special interest, through their similarity to the long-known contractions of the apex of the heart, separated and without ganglia, in blood-serum. The heart-muscles, it is known, are also striped.

THE GORILLA AND THE CHIMPANZEE.—Mr. H. von Koppenfels, who is now engaged in explorations in the Gaboon district of Western Africa, in a letter published in the last number of the *American Naturalist*, states that he has good evidence of the existence of crosses between the male gorilla and the female chimpanzee. "This," he says, "settles all the questions about the gorilla, chimpanzee, Kooloo-Kamba, N'schigo, M'bouvé, the Sokos, Baboots, &c." Herr v. Koppenfels observes that the "French *savants* seem to have a special predilection for creating new species from variations in the form of the skull, such as often occur in this group of animals. There is but one district which forms the range of the gorilla, and this is situated in the western part of Equatorial Africa, and here it exhibits no varieties, while the chimpanzee is found all over Tropical Africa, and naturally exhibits considerable variation. The chimpanzee of Northern Guinea differs essentially from that of the southern portion of the same country, and, according to Livingstone, the 'Soko' differs from both, but is still a chimpanzee. Du Chaillu's Kooloo-Kamba, N'schigo, and M'bouvé are *not* distinct species, and this traveller, who is certainly a man of merit, but is too credulous, has been imposed upon by the mendacity of the natives, which beggars description. The names N'schigo, M'bouvé, Koola, Baboo, Soko, Quia, and Kooloo-Kamba are only different designations of the chimpanzee by different tribes. The mongrel progeny of the male gorilla and female chimpanzee discovered by me is found but in individual cases, and as such deserves no special name."

SALIVARY GLOBULES.—Prof. Stricker of Vienna, by examination of salivary globules under high-power lenses (obj. No. X. of Krafft and Seivert), has obtained the following results:—He cannot accept the supposition of a so-called Brownian (molecular) movement in salivary corpuscles. He has found the globules to consist of a complete, distinctly visible network. The granules, which have been seen under low powers of the microscope, appear on close inspection and carefully focussing to be thickened points of intersection of the threads forming the reticulum. There is a permanent fluctuation of the threads during the life of the corpuscle. By the action of concentrated salt-solutions the fluctuation ceases gradually and the reticular arrangement disappears.

FISH MORTALITY IN THE GULF OF MEXICO.—From time to time since 1844 a widespread destruction of all sorts of marine creatures has occurred along certain well-marked-out tracts in the Gulf of Mexico. In 1854 the fishes suffered all along the southern shore; in 1878 there was again an excessive mortality; in 1879 the plague again appeared; while in 1880, we learn from the recently-published report of Inspector Ingersall to Prof. S. F. Baird, it has been very intense. The poisoned waters occur in streaks or patches, sometimes near to one another, at other times many yards apart. These seem to drift with the flow of the tide, and ultimately become diluted. The most probable solution of this strange phenomenon is to suppose that eruptions of noxious volcanic gases arise through the bottom of the sea; certain it is that the marine life on the sea-bottom suffers first. Sponges, sea-anemones, mollusks, and the ground fish die in mass, and apparently at once. Upwards the deadly pestilence mounts, and the small fish swimming at or near the surface are killed by thousands, and float lifeless on the water. The large surface fish would seem to escape, and rarely is a mullet to be found destroyed. Fishing in such districts has to be abandoned, even although in the pure streaks the fish abounded, for should a smack fill its well with the results of a successful catch it had to run the gauntlet of the broad patches of the poisoned waters, and if any of these were encountered, and entered the well, a few moments would suffice to bring about the death of every fish in the cargo. The keeper of the Egmont Lighthouse writes on February 21 in this year: "As the tide came in on October 17, 1880, there were thousands of small fish floating on the water, most of them quite dead. The next day the fish were dying all along the shore; between October 25 and November 10 the stench was so horrible that it was impossible to go on the beach. Sending my family to Manatee, the assistant-keeper and myself shut ourselves up in our rooms, and kept tar, coffee, &c., burning day and night in order to stand it. The peculiar smell was like bilge-water. The fish I noticed dying acted as if crazy, darting around in every direction, then giving up and floating ashore. After a very heavy gale from the south-west the bad and good waters got mixed up, and soon all the fish caught were fat and nice." As the cause of this strange phenomenon is still problematical, some discarding the idea of the evolution of subterranean gases, believing it to be the result of a poisoning of the waters by an excess of rain-water discharged into the Gulf by the rivers, others that it is owing to the water being saturated with the tannin derived from decomposing roots and stems of palmetto, sumach, oak, &c., it would seem highly desirable that Prof. Baird should institute a series of observations as to the chemical constituents at different times of the waters of these districts.

ON THE NECTAR-SECRETING GLANDS IN SPECIES OF MELAMPYRUM.—The cow-wheats are a familiar group of plants, of which several species are to be found native. E. Ráthay, while investing the subject of the secretion of sugar by plants, was attracted by the appearance of swarms of ants evidently collecting some sweet material from the little dark puncta on the bracts of *Melampyrum arvense* (purple cow-wheat). These puncta, even under a hand-lens, are seen to be little round disk-shaped bodies, which proved to secrete a sugary secretion for which the ants came. In a memoir on this subject these gland-like disks are described and figured as they occur in *M. arvense*, *M. nemorosum*, *M. pratense*, and *M. barbatum*. These bodies have long since been observed by the systematic botanists; they form part of the trichomic development of the epidermal system of the bracts, and may be described as consisting of a short foot-cell, attached to the centre of which is a circular disk. This latter is composed of a single layer of seven-sided cells. According to their function these structures in the species of Melampyrum mentioned belong to the epidermal glands of De Barry, since they secrete upon the upper side of their disk, between the cuticle and cell-membranes of the seven-sided cells, a liquid which, through the bursting of the cuticle, gets out, and is sought by the ants and eaten. The secreted fluid contains at least 2 per cent. of a kind of sugar which is not reducible by oxide of copper. The history of the development of these structures is practically the same as that of other similar formations. The purpose which they serve to the Melampyrum would seem neither to be explained by the hypothesis of Belt and Delpino as to the meaning of the extra floral nectaries, nor according to the hypothesis of Kerner concerning the same. Ráthay further adds that the moistness which almost always appears over these structures is quickly, on removal, renewed; that this moistness increases so much as to form drops when the plants are protected from the approach of ants, &c.; and that this drop-formation is repeated several times if the drops are from time to time removed (Vienna Academy *Proceedings*, vol. lxxxi. 1880).

CHEMICAL NOTES

M. RAOULT states in *Compt. rend.* that the oxides of barium, strontium, and calcium rapidly absorb carbon dioxide at a high temperature: much heat is evolved in the reaction, the temperature of the mass in the case of barium oxide being as high as 1200°, according to a pyrometric determination.

MM. CAILLETET AND HAUTEFEUILLE have determined the densities of liquid oxygen, nitrogen, and hydrogen (*Compt. rend.*) by liquefying these gases mixed with carbonic anhydride and with nitrous oxide, and basing their calculations on the assumption that the mixed liquids are without action on one another. The density of liquid oxygen at $-23°$ (pressure = 300 atmos.) was found to be 0·89 from experiments with carbonic anhydride, and 0·94 from experiments with nitrous oxide: at 0° the numbers obtained were 0·58 and 0·65 respectively. Liquid nitrogen at $-23°$ gave numbers corresponding with the density 0·44, while at 0° the density was 0·37. The density of liquid hydrogen was 0·033 at $-23°$, and 0·025 at 0°. Dividing the atomic weights of the three elements by the densities at $-23°$, the *atomic volume* of oxygen is found to be 17, of nitrogen 31·8, and of hydrogen 30·3.

HERR O. LÖW describes experiments with fluorspar from Wölsendorf (*Berliner Berichte*), which seem to show that the liquid contained in the cavities of this mineral consists of free

fluorine. When the mineral is broken up, a strong chlorine-like odour is perceptible; when heated with sulphur, an odour resembling that of sulphur chloride is evolved; the liquid in the mineral decomposes sodium chloride and iodide, with formation of chlorine and iodine respectively. On addition of dilute potash it yields a solution which instantly decolorises indigo solution. When the mineral is moistened with ammonia water, powdered, the liquid filtered off, neutralised with sodium carbonate and evaporated, a residue is obtained which, on addition of sulphuric acid, evolves hydrofluoric acid. Herr Löw thinks that the fluorine is produced by dissociation of cerium fluoride in the mineral.

THE application of potassium oxalate as a precipitant for many heavy metals, both in qualitative and quantitative analysis, is described by Herr von Reis in the *Berichte* of the German Chemical Society; the quantitative results obtained are very accurate.

THE reaction of bleaching powder on alcohol, which results in the formation of chloroform, is not thoroughly understood. M. Béchamp details experiments (*Annales Chim. et Phys.*), according to which no oxygen is evolved during the change, but only after the primary change is complete, and a secondary change begins when the reacting bodies have acquired a high temperature. The formation of chloroform is represented by M. Béchamp by the following equation, $2C_2H_6O + 4Ca(OCl)_2 = CaCl_2 + 2H_2O + 2Ca(OH)_2 + (HCO_2)_2Ca + 2CHCl_3$.

IN *Annali di Chimica* Signor Chiappe states that he has found spots of minium (Pb_3O_4) on various marble monuments, on parts of which bands of lead have been fastened. He supposes that by the action of the air and rain lead carbonate is produced, this is absorbed by the marble, and when exposed in places to the sun's rays it is decomposed with production of minium.

A VARIETY of coal, said to be the most highly-carbonised member of the coal series hitherto described, has been found near Schunga, on the western shores of Lake Onega (*Jahrbuch für Mineralogie*); it contains about 91 per cent. carbon, 7 or 8 per cent. water, and 1 per cent. ash. This coal is extremely hard and dense, has an adamantine lustre, is a good conductor of electricity, and has a high specific heat (0·1922). Although containing as much carbon as the best graphites from Ceylon, it is not a true graphite, inasmuch as it is not oxidised by potassium chlorate and nitric acid, but behaves towards those reagents like an amorphous coal.

FEDER AND VOIT have carefully repeated the experiments of Hallervorden on the effect of feeding with ammonium carbonate (*Zeitschrift für Biologie*). The results confirm the statement of the last-named author, that in dogs ammonium carbonate is converted into urea, and also show that ammonium acetate undergoes a similar change.

IT has been asserted that the employment of sodium nitrate in manures facilitates the solution and removal from the soil of plant-foods: Herr Fiedler has recently examined this subject experimentally, and he thinks himself justified in concluding that nitrates do not dissolve out any considerable quantities of plant-foods from the soil; that, within certain limits, absorption of phosphoric acid is favoured and absorption of potash slightly impeded by sodium nitrate; and that the same salt exerts a solvent action on *dibasic* phosphates of calcium, iron, and aluminium, but not on the *tribasic* phosphates of these metals.

GEOGRAPHICAL NOTES

AT the meeting of the Geographical Society on Monday last, Lieut.-Col. C. E. Stewart, of the Bengal Staff Corps, read some portions of a paper which he had prepared on the country of the Tekke Turkomans and the Tejend and Murghab Rivers. Col. Stewart, it may be remembered, is one of the officers who was accused, in a recent official despatch from St. Petersburg, of "haunting the oases" in the Turkoman country: this paper was consequently looked forward to with much interest. He left Constantinople in April of last year, and proceeded in the first instance to Ispahan, where he spent two months and a half in the Armenian quarter of Julfa, making preparations for his journey, as he had determined to travel in the disguise of an Armenian horse-dealer. On September 30 he went to Ardakan, where he assumed his disguise, and travelled in a north-easterly direction along the edge of the salt desert to Meshed, afterwards crossing the mountains to Mahomedabad. The account of this part of his journey, with its numerous adventures, Col. Stewart was unfortunately obliged to omit, owing to the length of his paper. Deregez, in which Mahomedabad is situated, is in the most northern part of North-east Persia beyond the mountains, and is some sixty-five miles long and forty broad; as it projects into the Turkoman country, it is a most favourable position for collecting information respecting the neighbouring country to the Caspian on one side, and to Merv on the other. Col. Stewart made Mohamedabad his head-quarters from November 25 to January 15, and during this time moved about in Deregez, but never crossing the Persian frontier, and obtained much interesting information by diligent inquiry among the Persian officials and the Turkomans whom he met. This particularly applies to the Merv district—for he denies the existence of a town of Merv—and the Murghab River. Col. Stewart also explained very clearly the Russian line of advance, and the present and future position of the railway question. It may be interesting to add that his disguise was completely successful, and entirely deceived even the Persian servant of Mr. O'Donovan, the enterprising correspondent of the *Daily News*, who is now detained in the Merv district.

THE fiftieth and last volume of the Geographical Society's *Journal* is chiefly occupied with Mr. C. R. Markham's history of the fifty years' work of the Society, which is at once valuable and entertaining. In it will be found detailed the actual circumstances attending the establishment of the Society, about which some misapprehension has hitherto prevailed. This took place in July, 1830, and the Society is therefore now fifty-one years old: after passing through many vicissitudes, which at one time threatened its very existence, it now numbers 3394 ordinary Fellows, and is the largest and wealthiest institution of the kind in the world. Mr. Markham, we may add, has been able to reproduce its first list of 460 Fellows, dated August 4, 1830. In a voluminous appendix, equal in length to the history, he furnishes complete lists of officers from the commencement, references to obituary notices of distinguished men, lists of explorers and geographers who have received medals, grants in aid of their work, &c., and of the papers and maps published by the Society. Lastly there is some interesting information respecting the Hakluyt Society. The few remaining pages of the volume contain notes on two maps of the Andaman Islands by Mr. E. H. Man and Lieut. R. C. Temple, and on the history and origin of the word "Typhoon," by Dr. F. Hirth, tables of altitudes in East Central Africa computed from 317 observations taken by Mr. Joseph Thomson during his recent East African expedition, and a narrative of a journey overland from Amoy to Hankow by Mr. E. F. Creagh. From a brief prefatory notice we learn that the issue of the *Journal* is to be discontinued, and that in future "elaborate papers of more than ordinary length and great value" will be published as supplements to the monthly *Proceedings*.

FROM the *Colonies and India's* Queensland notes we learn that Mr. Watson, in command of the Transcontinental Railway Survey, had crossed the Worna and Workingham Creeks in safety, and reported the soil magnificent and the grass splendid. The floods had however "sadly hampered the expedition," and this fully bears out the remarks made in NATURE, vol. xxiv. p. 114, as to the route for the line laid down on the Government map. It has lately been announced that General Fielding and Mr. J. Robinson, C.E., have gone out to make what is presumably an independent survey for a line, and we hope they may be able to find a more suitable route. The arrival of Mr. Watson's party at Point Parker, on the southern shore of the Gulf of Carpentaria, has since been announced by telegraph.

THE new *Bulletin* of the Bordeaux Society of Commercial Geography contains an address recently delivered before it by Capt. Gallieni, on his expedition, chiefly for surveying purposes, from the Senegal to the Niger. It is accompanied by a sketch-map of the region, on which the routes of the expedition are laid down.

PROF. ROWLAND'S NEW THEORY OF MAGNETIC ACTION

PROF. ROWLAND has lately published in the *American Journal of Mathematics* (vol. ii., No. 4; vol. iii., Nos. 1 and 2) a series of papers on "The General Equations of Electromagnetic Action with application to a New Theory of Mag-

netic Attractions, and to the Theory of the Magnetic Rotation of the Plane of Polarisation of Light." The papers, in addition to what is stated in their title, contain the mathematical consideration of that action of magnetism on electric currents which was lately discovered by Mr. Hall, and it is proved in them that, if Maxwell's theory of light be true, this action will explain the magnetic rotation of the plane of polarisation of light. These papers will no doubt be very extensively read, both on account of the interest of their contents and the great reputation of their author, and a brief discussion of them may therefore not prove uninteresting to the readers of NATURE.

We shall commence with the "New Theory of Magnetic Attractions." This theory is of the simplest kind, and obviously suggested by the mathematics of the subject. Since the magnetic induction is related to the distribution of the vector potential of magnetic induction in exactly the same way as the angular rotation of an element of fluid is to the distribution of velocity in the fluid, Prof. Rowland suggests that the magnetic field consists of a perfect fluid, whose velocity at any point is represented in magnitude and direction by the magnetic vector potential at the point, the vortex lines in this fluid are the lines of magnetic induction, and the velocity of angular rotation, is proportional to the magnitude of the magnetic force. Again, since 4π times the electric current is related to magnetic induction in the same way as magnetic induction to the vector potential, Prof. Rowland considers that an electric current consists of, as it were, vortices of vortices, or in other words, that certain irregular distributions of the vortices constitutes currents.

Maxwell has proved that the forces existing in the magnetic field could be produced by a certain distribution of stress in a medium filling the field. This stress in the simplest case consists of a tension along the lines of force equal to $\frac{H^2}{8\pi}$, along with a pressure at right angles to the lines of force equal also to $\frac{H^2}{8\pi}$, H being the intensity of the magnetic force.

Prof. Rowland goes on to show that this state of stress exists in the medium, which, according to his theory, fills the magnetic field; his proof is as follows:—"Conceive the fluid in a tube to be rotating around the axis with a certain velocity, and suppose the ends of the tube to be closed with movable pistons. Then, if the pistons are left free, there will be a centrifugal force against the sides of the tube proportional to the square of the velocity of angular rotation. If the walls are flexible and the piston immovable, then there will be a force tending to press the pistons in, and proportional also to the square of the velocity. According to our theory the magnetic force is the velocity of rotation, and so we have in the medium a tension along the lines of force and a pressure at right angles to them." Prof. Rowland does not seem to have noticed that this explanation requires the vortices to be of a finite size. It is easy to prove that in a cylindrical vortex of radius a, density ρ and angular rotation ω, the intensity of pressure on the circumference of the cylinder is greater than the mean intensity of pressure on the ends by $\frac{\rho\omega^2 a^2}{4}$; but if this is to explain the magnetic attractions the difference must be $\frac{H^2}{4\pi}$. Hence if $H = c\omega$, where c is a constant, we must have $\pi\rho a^2 = c^2$, $a = \frac{c}{\sqrt{\pi\rho}}$; we thus get a definite value for a, and the vortices must not be capable of division into bundles of smaller radius than a. Thus the fluid by which Prof. Rowland explains magnetic action cannot be the indefinitely divisible fluid treated of in theoretical hydrodynamics. It is worthy of remark that in the theory of magnetism put forth by Maxwell in the *Phil. Mag.* for 1861-62, and which agrees with the theory we are considering in explaining magnetic force by the angular rotation of a fluid, the vortices have a finite size, being done up as it were into cells, the space between the cells being filled with particles whose motion, according to Maxwell, constitutes electric currents.

Let us now go on to the explanation Prof. Rowland gives of the production of the magnetic field. He says: "Let the nature of electromotive force be such that it tends to form vortex-rings immediately round itself, not by action at a distance, but by direct action on the fluid in the immediate vicinity. The first ring will then move forward, another one will form, and so on until the whole space is filled with them, when there will be equilibrium." The consequences of this explanation, vague as it is, are somewhat startling. In the first place it is clear, from the properties of vortex motion, that every chain of particles of the fluid which possess rotation at any time must at some previous time have been in the immediate vicinity of the electromotive force; and since according to the theory there is rotation of the fluid at every point in the magnetic field, it follows that in the time taken to set up the field every particle of fluid in it has been in the immediate neighbourhood of the electromotive force. But magnetic disturbance is propagated, according to Maxwell's "Theory of Light" (which Prof. Rowland accepts), with the velocity of light; hence the streams of the fluid must be flowing with the velocity of light, and in addition every particle of fluid in the field must have rushed through the small space occupied by the seat of the electromotive force in the short time it takes to establish the magnetic field. Another difficulty which Prof. Rowland does not explain is the following: If we take a small element of electromotive force we know that to agree with the distribution of magnetic force all the vortex-rings must have the same sense of rotation; but if vortex-rings have the same sense of rotation they move through the fluid in the same direction, so that these vortex-rings when produced would all move off in the same direction, and thus leave one half of the field without rings, *i.e.*, without magnetic force. Again, the way in which these rings spread out so as to fill the field would seem to be in contradiction to the laws of vortex-motion; but as the author says he is investigating the dynamics of the subject, we may leave further comment on this point till the result of his investigation appears.

The explanation of the stress in the medium which we have referred to before is the only application of the theory worked out by Prof. Rowland. He does not explain by it any of the phenomena of induction, nor does he get from it any connection between statical and current electricity; yet he does not hesitate to speak of his theory "as one link in the chain, the first three links of which have been added by Thomson, Helmholtz, and Maxwell."

We must now leave this part of the subject and pass on to that portion of the paper which treats of the general equations of the electro-magnetic field. The mathematics of this is merely an application of the theory of the vector-potential to currents. The most important feature in the treatment of the subject is that Prof. Rowland always writes the product of the conductivity into the electromotive force instead of the intensity of the current, and claims that this is an important advance; but if there is any difference either Ohm's law must not be true, or Prof. Rowland must mean by electromotive force something different from that meant by ordinary users of the term. Prof. Rowland asserts that in an unlimited medium the action is not between magnets and currents, but between magnets and electromotive forces; he bases this assertion on the theorem that in an unlimited medium unclosed electric currents have no magnetic action. It is hard to see how this proposition can be true, for the current through any area is measured by the line integral of the magnetic force round the boundary of the area; but if the magnetic force is everywhere zero, then the line integral of it round any curve must vanish, and thus the current at any point must vanish. The proposition is based on reasoning of the following kind: the force between an electric point (by an electric point he means a point from which electricity is streaming, in fact what is usually called a source) and a magnetic pole must by symmetry be along the line joining them. But a magnetic pole of any size is always accompanied by one of the opposite sign, and the two form a vector quantity; and we think from the relation that one pole necessarily bears to another, it is not safe to reason about it as if it were a purely scalar quantity. Prof. Rowland himself acknowledges what is equivalent to this, for after saying that the force due to the unclosed currents on each pole of the magnet is zero, yet he says there is probably a force on the magnet as a whole tending to place it across the currents.

Although we think that the reasoning given for the assertion that the action is not between magnets and currents, but between magnets and electromotive forces, is unsatisfactory; yet we think that, understood in a certain sense, the proposition is mathematically true. For we can prove directly from the ordinary expressions for the magnetic action of currents, that if we have a source and a sink of equal intensities $(4\pi m)$ placed close together, the magnetic action of the currents produced is

the same as that due to a current of strength m flowing along the short line joining the source to the sink. Now the current at any point produced by a source and sink placed close together at a distance ds, is exactly the same as the magnetic force at the same point produced by a magnet joining the source and sink, whose moment is mds, and direction of magnetisation along the line joining the source and sink. Hence if we have any system of currents in the field, and find by the application of the methods given by Sir W. Thomson in his paper on "Inverse Problems" the distribution of magnetism which would produce a magnetic field such that the magnetic force at any point was equal in magnitude and direction to the current at the point, the magnetic action of the system of currents will by the proposition just stated be the same as that due to currents whose intensity and direction coincide with the intensity and direction of the magnetisation producing the said magnetic field. Thus instead of currents occupying the whole of the medium, we have only to consider currents occupying a limited portion of it. This is, we think, all that can be fairly stated about this point, and it will be seen that, to say the least, Prof. Rowland's statement that "the action in such a medium reduces itself to an action between magnets and electromotive forces instead of between magnets and currents," is not a clear way of putting it. Prof. Rowland in this part of the subject introduces a new term, viz., magneto-motive force; this is a force supposed to exist between two magnetic poles so as to cause the same number of lines of induction to pass between the points as to flow out of either of them; it is proportional to the magnetisation, and seems only introduced for the sake of making more evident the fact that currents are related to electromotive forces like lines of induction to magnetisation, or with the new terminology to magneto-motive forces. This was pointed out by Maxwell in his paper on "Faraday's Lines of Force" published in the Cambridge *Transactions* for 1856.

The last part of the paper, which is also the most interesting, contains the explanation, by means of the new action discovered by Mr. Hall, of the magnetic rotation of the plane of polarisation of light. By adding to the old expression of the electromotive force a term representing the force discovered by Mr. Hall, Prof. Rowland obtains an expression for the rotation of the plane of polarisation of exactly the same form as the one given by Maxwell in § 829 of the "Electricity and Magnetism."

J. J. THOMSON

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

CAMBRIDGE.—The report of the Botanic Garden Syndicate states that during the past year valuable additions have been made to the collections of ferns and orchids, and many choice stove and greenhouse plants have been received. The collection of hardy, herbaceous, and alpine plants has been much increased, and the rockery furnished with many rare alpine species. The genera Iris, Narcissus, and Helleborus have received special attention. During the year, 1594 labels have been written in large letters. The curator, Mr. Lynch, has extended the correspondence of the Gardens with botanic gardens, nurserymen, and private cultivators: 2600 plants have been received, and 1285 packets of seeds.

In consequence of the decision of the Duke of Devonshire in favour of the legality of the recent vote of the Senate admitting women to the Previous and the Tripos Examinations, the first lists in which the names of women who have passed the Previous and any Tripos Examination, have appeared in the University *Reporter*. In the Natural Sciences Tripos, Part I, Class 2, is the name of Miss Anelay of Girton. In the Previous Examination twelve Girton students and two Newnham students have passed in one or more parts of the examination.

LOCAL LECTURES.—In spite of the removal of several important districts from the scope of these lectures by the establishment of local colleges, the numbers attending lectures during the past winter have been 4369 as against 5009 in the preceding winter; and the reduction in numbers is due to the absence of the South Wales centre from the lists, the Syndicate having been unable to make adequate arrangements for this district, owing to their engagements elsewhere. South Wales is again to be vigorously worked in the coming session. Dr. R. D. Roberts of Clare College has been appointed Assistant Secretary for the purposes of the local lectures. The courses of lectures on physical science subjects in the past winter have included Mr. Teall's on Early Man in Western Europe, and the Origin of Rocks and Scenery of the British Isles at Nottingham and Derby, Mr. J. E. Marr's on Geology at Carlisle and Penrith, Mr. E. Carpenter's on the Science and History of Music at Nottingham, and on Light at Chesterfield, Mr. Carr Robinson on Gases and on Chemistry at Hull, and by Mr. H. N. Read on Botany at the Crystal Palace.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 16.—"On the Reversal of the Lines of Metallic Vapours. No. VIII. (Iron, Titanium, Chromium, and Aluminium.)" By Professors Liveing and Dewar.

In their last communication on this subject the authors observed that iron introduced as metal or as chloride into the electric arc in a lime crucible in the way which had proved successful in the case of many other metals, gave no reversals. They succeeded however in reversing some ten of the brightest lines of iron, mostly in the blue and violet, by passing an iron wire through one of the carbons, so as to keep up a constant supply of iron in the arc. Considering the great number of iron lines, and that so many of them are strongly represented amongst the Fraunhofer lines, it seemed somewhat surprising that it should be difficult to obtain a reversing layer of iron vapour in the arc inclosed in an intensely heated crucible. A like remark might be made respecting titanium, which is almost as well represented as iron in the Fraunhofer lines, but has heretofore given no reversals. Almost the same might be said of chromium, except that the number of chromium lines is so much less than that of either of the other two metals.

They have since found that most, if not all, of the strong lines of these three metals may be reversed by proper management of the atmosphere and supply of metal in the crucible. Indeed with regard to iron the method employed with other metals was successful so far as the ultra-violet rays were concerned, though it failed for less refrangible rays. When iron has been put into the crucible through which the arc of a Siemens' dynamo-electric machine is passing, and then fragments of magnesium dropped in from time to time, most of the strong ultra violet lines of iron are reversed. The magnesium seems to supply a highly reducing atmosphere, and to some extent carry with it the iron vapour. It also produces a good deal of continuous spectrum, at least in certain regions, and against this the iron lines are often depicted on the photographic plates sharply reversed. In this way the authors have observed the reversal of the strong

iron lines about the solar lines L and M, four strong lines below N, the line O, all the strong lines from S_2 to U inclusive, and two strong groups still more refrangible.

Potassium ferrocyanide introduced into the arc instead of magnesium gives a reversal of the same lines as are mentioned in the foregoing paragraph.

Iron wire fed in through a perforated pole gives reversals of the highest group (wave-length 2492 to 2480), but with the lines so much expanded as to form broad absorption-bands instead of lines.

With a vertical arrangement of the carbons and a stout iron wire in the axis of the lower (positive) carbon, many more lines in the visible part of the spectrum are seen expanded and reversed. This effect is sometimes enhanced by leading into the crucible through the upper carbons, which is perforated for the purpose, a very gentle stream of hydrogen gas; the stream must be no more than is just sufficient to give a tiny flame at the mouth of the crucible; a stronger stream diminishes the amount of metallic vapour, probably by its cooling action, and lessens the effect. By this treatment some of the strongest lines of iron remain reversed for some time, the weaker lines are seen to expand and be reversed for a few seconds at a time, when, from a change in the intensity of the current, or some other reason, a larger amount of metal is volatilised and shows itself by burning in brilliant scintillations at the mouth of the crucible.

A list of the iron lines reversed, 136 in number, designated by their approximate wave-lengths, is given in the paper.

When the perforation of the lower carbon is filled with titanium cyanide instead of the iron wire the titanium lines come out very brilliantly and steadily, and many of them, especially in the green and blue parts of the spectrum, are expanded and reversed. A list of twenty-nine lines observed to be reversed is given in the paper.

In the case of chromium, introduced into the crucible either as oxide or as bichromate of ammonia, there were no reversals until a gentle current of hydrogen or of coal gas was led in through the perforated carbon. This brought out the triplet in the green, wave-lengths 5207, 5205, 5203, sharply and steadily reversed, and likewise the three strong lines in the indigo, wave-lengths 4289, 4274, 4253; also a triplet near N at wave-lengths about 3578, 3593, 3606, apparently coincident with strong lines in Cornu's map of that part of the solar spectrum, and a rather strong double line just below O at about wave-length 3446. The reversal of another chromium line at about wave-length 3217 is doubtful. A triplet at wave-lengths 2799·8, 2797, 2794, is more easily reversed than any other of the chromium lines. This triplet is generally strongly developed whenever a compound of chromium is introduced into the crucible, so that the authors conclude that it is due to that metal, but it is sometimes visible in the photographs when other chromium lines are not seen. A still more refrangible chromium line, wave-length about 2779·6, is also frequently reversed by a gentle current of hydrogen.

The two aluminium lines near S are frequently reversed when a fragment of the metal is dropped into the crucible, the less refrangible line, wave-length 3091·5, being more strongly reversed, and continuing reversed for a longer time than that at wave-length 3080·5.

Chemical Society, July 16.—Prof. Roscoe, president, in the chair.—The following papers were read:—On the isomeric acids obtained from coumarin and the ethers of salicylic aldehyde, by W. H. Perkin. The author has studied the action of various agents on these bodies. The α body (from coumarin) is converted into the β body by heat or light. In general the effect of chemical action on the α acid is to convert it into the same compound as that yielded by the β body. Bromine forms an exception, and two isomeric dibromides were obtained. The author concludes that as the α body has a lower boiling-point, density, refractive index, and is less stable than the β acid, it is probable that its molecules are farther apart and that the difference of distance is probably between the radical and the hydroxyl. The derivatives from propionic and butyric coumarin were studied.—Notes on naphthalene derivative, by H. E. Armstrong and G. Lowe. The authors have continued their investigations as to the action of sulphuric acid on naphthalene, and confirm their previous statement that three and not two disulphonic acids may be obtained. An isomeric β naphtholsulphonic acid was prepared by dissolving β naphthol in cold concentrated sulphuric acid.—On the synthesis of ammonia, by G. S. Johnson. The author reasserts that pure nitrogen, free from nitric oxide, when passed with hydrogen over spongy platinum, forms ammonia. If however the nitrogen be previously passed through red hot asbestos no ammonia is formed. This indicates the existence of an active allotropic nitrogen analogous to ozone.—On the alkaloids of nux vomica, by W. A. Shenstone. The author has prepared pure brucine, but concludes that the so-called Igasurin has no existence.—Notes on photographs of the ultra-violet emission spectra of certain elements, by W. N. Hartley.—On the sulphates of aluminium, by S. U. Pickering.—On two new oxides of bismuth, by M. M. P. Muir, Bi_2O_7 and Bi_4O_7, prepared by the action of aqueous potassium cyanide on a hot nitric acid solution of bismuth nitrate.

Royal Microscopical Society, June 8.—The president, Prof. P. Martin Duncan, F.R.S., in the chair.—Eleven new Fellows were elected and proposed.—Prof. Paul Reinsch attended the meeting and exhibited specimens of the vegetable forms found by him in the Coal measures.—The president read a paper on some remarkable enlargements of the axial canal in sponge spicula and their causes, accompanied by drawings on the blackboard. Nearly all the spicula obtained from specimens of very deep soundings off Japan were found to have the normal axial canal enlarged in a moniliform or conoidal manner, producing very elegant results. The spicula were of seven or eight kinds, and were mature. The enlargement was found to be invariably accompanied by an open condition of the axial canal or by penetrations, cylindrical in outline, from without, down to the canal. The penetrations were shown to be connected with an organic body resembling the zoospores of an *Achlya*, and granules, organic in nature, were observed within the enlarged canals. Thinning and solution of the spicula, the result of these organisms, were considered, and admitting the influence of great pressure, the president stated that he had never seen anything which led him to believe that there was free carbonic acid gas in the ocean.—A note was read by Dr. Savage calling attention to the changes which took place in nervous tissues in the process of hardening.—Mr. Holmes read a paper on a new British Alga, specimens of which were exhibited.—Discussions also took place on the value of swinging sub-stages on the motion of diatoms.—Dr. Maddox exhibited some micro-photographs of diatoms, and Mr. Powell demonstrated the aperture of his $\frac{1}{5}$-inch oil-immersion objective = 1·47 num. ap., the largest hitherto made.

Physical Society, June 25.—Prof. Fuller in the chair.—Señor Olympio de Barcelos was elected a member.—Mr. Grant exhibited an apparatus for showing the position and direction of the curve of zero electro-dynamic induction. It consisted of two coils of insulated wire mounted on stands, one being fixed while the other was free to revolve round it at a fixed distance.—Prof. W. E. Ayrton explained the determination of the refractive index of ebonite made by himself and Prof. Perry. The result for oxy-hydrogen light was 1·7, but at the suggestion of Prof. Fitzgerald of Dublin this was checked by measuring the polarising angle of ebonite by reflected light. Sunlight was employed in these experiments, and different pieces of ebonite. The result was 1·611. Professors Ayrton and Perry had repeated their former experiments, using the electric light and a battery of 70 volts E.M.F. The result confirmed the one first obtained. They had also determined the index of refraction in the ordinary way from the red rays, which they observed to pass through the prism of ebonite. Result for the least refrangible rays 1·66. Mr. Boys remarked that one could see better through thin ebonite if it was varnished or wetted than when untreated.—A letter was read by the chairman from a sub-committee of the British Association inviting the members of the Society to send exhibits to the jubilee meeting of the British Association at York.—Dr. James Moser read a paper on the microphonic action of selenium cells, in which he argued that the action of the selenium cell in the photophone was that of a microphonic contact or bad joint between the metal electrodes or metal plates of the cell and the selenium. The heat rays of the photophonic beam caused the joint to expand and contract; hence the variation in the current passing through the receiving telephone. Dr. Moser also exhibited a piece of selenium which increased, not diminished, in electric resistance when light fell upon it. He further showed a standard Daniell cell of the gravity type, which consisted of a glass vessel containing the copper plate at the bottom immersed in sulphate of copper solution, and the zinc plate at the top immersed in sulphate of zinc solution, and a clear line of demarcation between these solutions was produced by suspending an independent piece of zinc midway between the plates, so as to decompose all the sulphate of copper which diffused upward to that point.

Prof. Mcleod said that he had produced the same result by surrounding the zinc plate with a cage of copper wire connected to the copper plate. Copper deposited on the cage and the cell was in constant use. Dr. Lodge said that arrangement would not however serve as a standard of electromotive force, because all the copper plate should be in the copper solution. In his cell the copper and solution are both in a test tube immersed in the zinc solution, and diffusion has to take place up this test-tube and down the cell so as to enter a second tute, open at the bottom, in which the zinc is placed.—Dr. Guthrie showed a new experiment to the effect that when a magnet is suspended over a disk of copper and the disk is rotated the magnet is repelled upwards. The experiment was shown by suspending a horse-shoe magnet from one end of a scale beam, counterweighted. As a possible explanation he suggested that the vertically-resolved force of the induction-current before the magnet might be greater than that behind the magnet.—The Secretary read a paper by Prof. Balfour Stewart and Mr. W. Strode, on results obtained by a modification of Bunsen's calorimeter described to the Society in January last year. With a new instrument made by Casella they have determined the mean specific heat of iron to be 0·1118, and that of sulphur 0·1756, the true values being given as 0·1138 and 0·1776. The advantage of the method is its simplicity, and the fact that very small quantities of the substance may be used.—Dr. Lodge then explained experiments by Mr. Sutherland, showing that a Daniell cell keeps its E.M.F. very constant when heated, because the thermo-electric effect at the junction of the zinc with the solution is balanced by that at the junction of the copper with the solution. After remarks by Dr. Moser and Prof. Perry, the Society separated until November next.

PARIS

Academy of Sciences, June 20.—M. Wurtz in the chair.—The following papers were read:—Observations on the simultaneous reduction of two bilinear forms, by M. Jordan.—On the preparation of aldol, by M. Wurtz.—Fresh discovery of native sulphur in the soil of Paris, by M. Daubrée. This occurred during the laying of drains in the rue Meslay. The case seems very similar to that previously recorded.—On a new thermograph, by M. Mercadier. The instrument consists of a cylindrical brass reservoir prolonged into a capillary tube of red copper, which opens into a Bourdon tube. The whole is filled with oil, and closed. The dilatation or contraction of the oil with varying temperature affects the curvature of the Bourdon tube, and thereby a recording lever. Two such instruments may be used simultaneously to give the curves for a deep and a peripheric part of the body. It is proved that in vaso-motor disorders the animal temperature undergoes variations in opposite directions in the central and peripheric parts. Inanition cools both the centre and periphery, while certain maladies seem to increase the production of heat, for they heat both parts.—On M. Roudaire's project of the interior sea; reply to M. Cosson, by M. de Lesseps.—On osseous grafts, by M. Ollier. He calls attention to Mr. MacEwen's success (in Glasgow) in reconstituting a portion of the humeral diaphysis by means of six cuneiform bony fragments taken from the tibias of young children having rachitic incurvations. The osseous tissue was transplanted complete. The antiseptic method was employed. (A note by Mr. MacEwen describes his mode of procedure).—Microscopic phenomena of muscular contraction; transversal striation of smooth fibres, by M. Rouget. It is demonstrated that this striation (which occurs only in the state of contraction) is due to the fibre when it contracts getting folded on itself, and then presenting alternate projections and depressions. The fibre-cells in polarised light are uniformly bi-refringent in the smooth state, but in the state of contraction they show in the dark field an alternation of bright and dark bands. It is shown from smooth fibres of the adductor-muscle of the valves in a cephalous molluscs killed by heat, that a fibre which has lost all contractility may still acquire all the peculiarities of structure and optical characters of striated fibres, if any cause produce in it fine and regular folds.—On the thermal laws of the excitative spark of condensers, by M. Villari. The heat developed by this spark (which is that produced against the exciter) is proportional to the quantity of electricity multiplied by the electric thickness, or it is proportional to the quantity of electricity for the fall of potential.—On the heat of formation of oxychloride of calcium, by M. André.—Action of protoxide of lead on alkaline iodides, by M. Ditte.—On the basic carbonates of lime, by M. Raoult. The property of hardening in contact with water is observed in all basic carbonates obtained by heating any lime, pure or not, in carbonic acid, and it is this that chiefly characterises that class of compounds.—Influence of concentration of hydrochloric acid on the dissolution of chloride of silver, by MM. Ruyssen and Varenne. The decrease of solubility as the acid is diluted is rapid and regular. The insolubility seems approximately to be tripled as the titre of the acid is halved.—Action of arsenic and phosphoric acids on tungstates of soda, by M. Lefort.—Researches on tertiary monamines; action of heat on bromide of allyltriethylammonium, by M. Reboul.—On the microzymas of chalk; reply to MM. Chamberland and Roux, by M. Béchamp.—Studies on the coal-formation of Commentry; its formation attributed to transport in a deep lake, by M. Fayol. He here criticises adversely the theory of primitive horizontality of the deposits with general subsidences of the ground. The natural explanation is transport without subsidence. Important industrial interests depend on arriving at an exact theory of formation of coal strata.—M. Daubrée presented the first volume of *Annals* of the School of Mines of Ouro-Preto, sent by the Emperor of Brazil in name of M. Gorceix. This describes some of the mineral riches of Brazil.—M. Tabourin communicated a project for the electric light; he would place in the pedestal supporting the carbons a small magneto-electric machine driven by the force of water in pipes, or by compressed air, or by descent of a weight.

VIENNA

Imperial Academy of Sciences, June 17.—L. T. Fitzinger in the chair.—T. Exner, examinations into the localisation in the cortex cerebri of man.—A. Rollett, on the action of salts and sugar on the red-blood corpuscles.—L. Boltzmann, contributions to the theory of viscosity of gases.—On some theorems relating to heat-equilibrium, by the same.—Ign. Klemencic, on the deadening vibrations of solid bodies in liquids.—Dr. K. Friesach, on the transits of Mercury and Venus in 1881 and 1882.—G. Haberlandt, on the collateral vessels in the leaves of ferns.—T. Herzig, contributions to the knowledge of trigenic acid.—A note on cyanuric biuret, by the same.—H. Fürth, on berberonic acid and the products of its decomposition.—G. Goldschmidt, on some new aromatic hydrocarbons.—C. Senhofer, on the direct action of carboxyl groups on phenols and aromatic acids.—C. Senhofer and F. Salay, on the action of hydroquinone on potassium dicarbonate.—C. Brunner, on the action of tolu-hydroquinone on potassium dicarbonate.—T. Zehenter, on some derivates of α-dioxybenzoic acid.—D. T. Woldrich, second report on the diluvial fauna of Zuzlawitz near Winterberg (Bohemia).—T. Pernter, on the daily and yearly course of atmospheric pressure on mountain-summits and in Alpine valleys.

BURMEISTER'S "MAMMALS OF THE ARGENTINE REPUBLIC"

Description Physique de la République Argentine d'après des observations personnelles et étrangères. Par Le Dr. H. Burmeister. Traduite de l'Allemand avec le concours de E. Daireaux. Tome III. Animaux Vertébrés: première partie, Mammifères, vivants et éteints. Royal 8vo. (Buenos Ayres: P. E. Coni, 1879.)

THE veteran naturalist, Dr. Burmeister, has devoted the third volume of his great work on the Argentine Republic to an account of the Mammals, recent and fossil, of his adopted country. As regards the latter series it is well known how long and how laboriously the author has worked on the extinct Mammalian Fauna of Buenos Ayres, and what excellent results have followed on his investigations. The summaries of his various memoirs on this subject contained in the present volume will therefore be much appreciated by those who may not have leisure or opportunity to refer to the originals, and will be especially useful in bringing the chief results already arrived at in a convenient shape before future explorers. Although so much has already been done in this direction, there are few countries in the world that still offer such a promising field for the palæontologist as the pampas of the Argentine Republic, where in certain spots bones of *Megatherium*, *Glyptodon*, *Macrauchenia*, and other extinct monsters seem almost to strew the upturned soil!

As concerns the recent Mammals of Buenos Ayres, Dr. Burmeister has also given us a very useful work, the only previous available authority on the subject being the summary of the Mammal-Fauna contained in the same author's second volume of his well-known "Travels" in the Argentine Republic, which is neither so full nor so complete. But we fear there is also still much to be done before this branch of the subject can be deemed to be satisfactorily known, and that Dr. Burmeister has not in every case made himself acquainted with the most recent investigations published upon several points.

In the first place, as regards the general arrangement of the Mammalian series, Dr. Burmeister will forgive us if we point out that he is a little behind the age. The Cuvierian division of the class into "Unguiculata," "Ungulata," and "Pinnata" was no doubt most in vogue thirty years ago, but we cannot agree with our author that it is still adhered to by "la plupart des zoologistes modernes." It is certainly strange to zoologists of the present day to find, in a work dated 1879, the Marsupials located in the centre of the placental series, and the Seals divorced from the other Carnivores. Again, on referring to the accounts of the more obscure groups of Bats and Rodents, we find a disposition to quote from Rengger and the "Voyage of the *Beagle*" instead of giving particulars obtained from modern specimens. Surely the Museo Publico of Buenos Ayres must have a well-arranged and properly-determined series of the native Mammals, whence particulars respecting their ranges and variations might have been taken.

The recent Mammals of the Argentine Republic, according to Dr. Burmeister's enumeration, are about 112 in number. Of the Quadrumana only four species intrude into the northern provinces, where alone forests are met with, the American monkeys being exclusively arboreal in habits. Of Chiroptera Dr. Burmeister allows twenty species, but there are doubtless more to be discovered when the fauna is worked out. The Feræ are twenty-one in number, embracing the jaguar and puma, both of which extend all over the Republic, and five other smaller species of *Felis*, besides seven different dogs of peculiar types. Five opossums of varying sizes constitute the Marsupial fauna of the Argentine Republic, and are succeeded in Dr. Burmeister's classification by twenty-seven Rodents—here, as is usual, except in Australia, the most numerously represented order of Mammals. Amongst them are the two most characteristic animals of the Argentine pampas—the Patagonian cavy (*Dolichotis patachonica*) and the Vizcacha (*Lagostomus trichodactylus*), which are spread over the whole Republic. The recent Edentata are represented by seven armadillos and two ant-eaters—a feeble remnant of the huge monsters of the same group that once existed in the country. Amongst these the most remarkable is the Pichy-ciego (*Chlamydophorus truncatus*), found in sandy dunes of San Juan and Mendoza, of which, and its singular habits, Mr. E. W. White has lately given us a most interesting account.[1] This diminutive burrowing armadillo is indeed one of the marvels of the class of Mammals. Such are its fodient powers, says Mr. White, "that a man has scarcely time to dismount from his horse before the creature has buried itself to the depth of its own body."

In Ungulates, like the rest of the neotropical regions, the Argentine territory is poor. Dr. Burmeister enumerates only ten, of which one-half are deer of the American type *Cariacus*. Besides these there are only two lamas, two peccaries, and the ordinary tapir of the lowlands (*Tapirus suillus*), which occurs in Tucuman and Corrientes, and concludes the terrestrial Mammal-fauna. Amongst the marine Mammals or "Pinnata," with which Dr. Burmeister, following Cuvier, concludes his list, are included two Seals and fourteen Cetaceans. One of the former (*Otaria jubata*) is well known in this country from the living examples in the Zoological Gardens. The latter have as yet been but imperfectly studied, and several of the species mentioned appear to be rather doubtful.

An atlas, intended to accompany this volume of Dr. Burmeister's important work, is announced to appear in *livraisons* at a later date.

THE ARABIAN DESERT

Gleanings from the Desert of Arabia. By the late Major R. D. Upton. (London: C. Kegan Paul and Co., 1881.)

THE author of this volume was an enthusiastic admirer of the Arabian horse, and seems to have visited the Arab tribes in the neighbourhood of Aleppo and Damascus with the single purpose of seeing and purchasing high-bred animals and acquiring information about the breed. The narrative part of the book is not furnished with dates, but from incidental remarks it appears that Major Upton was at Aleppo in 1875 and at Damascus in 1878. On the former occasion he journeyed

[1] *Proc.* Zool. Soc. 1880, p. 8, "Notes on *Chlamyphorus truncatus*," by E. W. White, F.Z.S.

eastward as far as the Euphrates, but does not seem to have descended below Balis, or to have ever been more than two days' journey from Aleppo. On this tour the traveller was mainly among half-settled tribes, and at the season of his visit the great hordes of pure nomads who sometimes pasture their flocks in the district had withdrawn to the south. Of the author's excursion from Damascus he gives no topographical detail. It was simply a visit to an encampment of the Eastern Anazeh.

From the limited range of these journeys, and from the fact that the writer made no exact observations except on his favourite subject, it will readily be understood that the book has little merit as a record of travel. Except in the matter of horseflesh, Major Upton merely describes in the loose manner of the amateur traveller whatever happened to amuse or strike him as he moved from place to place. He is neither an archæologist nor a naturalist; and though there is no doubt a great deal still to be learned about the less public customs even of the Arabs of the Syrian desert, who have been often visited by good observers, it is not surprising that Major Upton adds nothing on this head to what has been given to us by Burckhardt, and more recently by Lady Anne Blunt and her husband. Some facts may perhaps be gleaned from the remarks upon individual tribes and families, but even here the book is inferior to Lady Anne Blunt's "Bedouin Tribes," while the proper names are printed in such an inaccurate transcription that they must be used with caution.

Of the three parts into which the volume is divided the first and a small part of the second are personal narrative. The main bulk of the second part should have been altogether cancelled, for it consists, not of gleanings from the desert, but of gleanings from Pococke's "Specimen" and the extracts from Abulfeda printed at the close of White's edition of that work. The author, whose credulity is displayed in the earlier pages of the volume by an excursus on the Great Pyramid, based on conversations with a missionary of the Pyramid religion whom he met going out to preach to the heathen, accepts the whole mythical history of Arabia as sober fact, and as he has a theory that it throws great light on the parallel history of the Arabian horse, we are treated to some eighty pages of abridgment and excerpts from Pococke (generally without acknowledgment of the source). Unhappily, Major Upton's knowledge of Latin is that of a backward schoolboy. He frequently misses the meaning of his author, and, to make matters worse, the book has been so carelessly revised for press by the friend who undertook to superintend the posthumous publication that *inquit Jalalo'ddinus* becomes *inquib Jalabó dainus*, El Makîn, El Maka, and so forth, while the words *lingua Arabica qua coelitus descendisse Alcoranus dicitur*, with the marginal note *in Alcor. Sur. XVI.* become "the Arabic language in which the heaven-born Alkoran is said to be descended in Alk." The author is not stronger in Arabic than in Latin, as may be judged from the fact that he derives Hijâz from Hajar, *a stone*, and Kheil, the generic name of the horse, from the pigment Kohl. No reliance therefore can be placed on the transcription of Arabic words, and here again errors of the press have conspired to produce results truly appalling. Of the names of the seven mares of the prophet, for example, not one is quite correct, and the errors include such monstrosities as Sekh for Sekb, Sizez for Lizâz, Haif for Lakhîq. In brief, everything that our author derives from books, and all the historical and geographical speculations which he is so fond of, are absolutely worthless. This blemish affects even the third part of the book, where Major Upton deals with his proper subject, the horse. For his actual observations on the strains of pure Arabian blood are hopelessly entangled with fabulous legend and baseless theories. It is to be observed, moreover, that he admits that his own reading of the information derived from the Anazeh did not always accord with the views of the friend who accompanied him on his journey, an inhabitant of the verge of the desert, and long familiar with the Bedaween. Yet it is clear that Major Upton's knowledge of Arabic was by no means sufficient to enable him to take up an independent position in such matters. Like most men with a hobby, he had a theory to which facts must bend. But what a theory! Nothing less than a mythical history of the Arabian horse, the purest strains of which he traces back first to the time of David, when "the horses of his ancestors were entailed on" Rabí'atu-'l-faras, and then to Salâmân, the fourth in descent from Ishmael. That all authentic notices of the horse in Arabia point to a comparatively late introduction of that quadruped is of course indifferent to our author, who presumably had never heard of the researches of Hehn, Guidi, and others in this field.

Probably no European except Mr. Blunt can speak with real authority on the complicated subject of Arabian horse-breeding. Major Upton however takes no notice of what Mr. Blunt has written so well and fully on the topic, and on points where the two accounts diverge the uninitiated will hardly fail to prefer the clear and lucid statements of one who saw far more of the desert and is not biassed by theory. Lovers of the horse will however peruse with interest Major Upton's notes on the characteristic features of the Arabian breed illustrated by descriptions of individual animals.

W. Robertson Smith

OUR BOOK SHELF

Easy Lessons in Botany, according to the Requirements of the Revised Code, 1880. By the Author of "Plant Life." (London: Marshall Japp and Co., 1881.)

Neither better nor worse than the innumerable other little books of the same kind. The morphological part consists of the usual enumeration of descriptive terms, with coarsely-executed diagrams. The histology and physiology are very weak. The cell-nucleus is defined (p. 27) to be "a portion of the protoplasm denser than the rest," which may or may not be the case, but we are further informed, which is a more doubtful statement, that "it is this part of the protoplasm which grows." The following is at any rate a dogmatic way of stating the facts:—"By the addition of nitrogen and sulphur (taken up in water by the roots) to the constituent parts of starch, protoplasm has the power of forming *albumenoids*" (*sic*). If this is in accordance with the requirements of the Revised Code it only shows what tyranny in science is compatible with free institutions. On p. 32 we learn that "carbonic acid gas . . . finds its way . . . into the *spiral* vessels, which convey it to the cells of the *fibro-vascular* bundles." Very good; the Revised Code ought to know. But surely as a matter of argument there is a screw loose about the following sentence:—"As the store of albumen

is undivided the grain of wheat is said to be *Monocotyledonous*" (p. 42). Not even the solemn name of the Revised Code can enable us to digest this without distress.

Plant-Life. Popular Papers on the Phenomena of Botany. (London: Marshall Japp and Co., 1881.)

THIS is a most attractive-looking book by the same author as the dismal little tractate just noticed. It might have been hoped that it would have made clear some of its dark sayings. But they all seem to be *ipsissimis verbis*, sugared over with copious extracts from all sorts of people, from Thoreau and Kingsley to Mr. Worthington Smith, Dr. Masters and Mr. Darwin. On p. 30 we have "The carbon absorbed from the air is combined with the cell-sap and forms a substance called starch," which is even harder doctrine than anything in the "Easy Lessons." Much is said about *Equisetaceæ* and the hygroscopic movements of the elaters of their spores. An unfortunate microscopist is quoted from *Science Gossip* of such a remote date as 1878, who is of opinion that "the ultimate cause of this movement is quite unknown . . . . most probably it takes place by the contraction and expansion of the cells of which the elaters are composed." Of course it is well known that the spores are unicellular and the elaters are simply strips of the spirally torn outer cell-wall. The book, with all its blundering accounts of *Englena* (sic), *Claydonia* (sic), the "lovely *Closterium*" which "consists of two cells," and the like, may stimulate the curiosity of those who know nothing of plants to know more and better. It is at any rate interesting to find that Prof. Schwendener's lichen-theory has found its way to popular books, even though it is introduced with the remark that "concerning" gonidia "a humorous theory was promulgated a few years ago, but met with the ridicule it deserved." The book has 148 illustrations drawn by the author, which scarcely do justice to the "specially prepared rolled paper" provided for them.

The London Catalogue of British Mosses and Hepatics. Published under the direction of the Botanical Record Club. Second Edition. (London: David Bogue, 1881.)

THIS is a handy list on the well-known model of that formerly issued by Mr. Hewett Cottrell Watson for British flowering plants. It gives the distribution through the eighteen provinces into which Mr. Watson divided Great Britain for the purpose of ascertaining the range of British plants.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.]

Dr. W. B. Carpenter and Mr. W. I. Bishop

I AM sorry to find that Dr. Carpenter is "greatly surprised" at my allusion to the effect which has been produced by the circulation of his letter to Mr. Bishop, for in making that allusion I was under the impression that this letter had been put to a use other than that which Dr. Carpenter could have either intended or desired. If, as it now appears, I was wrong in entertaining this impression, it is needless to say that I am willing to apologise for having so far given it public expression; and in this case I can only infer that my error arose from an unfortunate difference in the estimate which we have respectively formed touching the scientific importance of the phenomena which Mr. Bishop has displayed. Such physiological and psychological interest as these phenomena present appeared to me to call for investigation in the ordinary way, *i.e.* by one or a few competent persons; it did not occur to me that they were of so much scientific value as to call for such "an assembly of gentlemen" as that which met at Bedford Square. Therefore, in writing my report, I took it for granted that Dr. Carpenter would have concurred in the "regret" which I expressed that his friendly recommendation should have been, as I thought, so far misused by Mr. Bishop as to constitute a general advertisement to scientific men; and my expression of regret was thus intended to show that I did not suppose Dr. Carpenter was to be considered intentionally responsible for the excitement which Mr. Bishop has succeeded in creating. It would no doubt have been wiser had I ascertained Dr. Carpenter's views upon this subject before assuming that they were the same as my own, and I do not yet quite understand whether he considers Mr. Bishop's manifestations worthy of all the attention which they have received. But in any case I hope that Dr. Carpenter will accept as more satisfactory an expression of further "regret," when I say I am very grieved to find that my allusion to his relations with Mr. Bishop, although intended as a friendly allusion, does not appear to have met with his approval. GEORGE J. ROMANES

Re W. I. Bishop

LET any one read carefully Dr. Carpenter's account of the card trick exhibited to him by Mr. Bishop; let him suppose that Mr. Bishop had two packs of cards, the one an ordinary pack for exhibition to the company, and the other a pack containing fifty-two cards, all alike (the backs of both packs being of the same pattern). Let Mr. Bishop now perform the trick with cards from the latter pack, and his success can be readily explained. But grant that Mr. Bishop had only one pack of ordinary cards: even then it is possible that the explanation of the trick is not hard to find.

Dr. Carpenter allows that Mr. Bishop *may* have known where the selected card was placed. Take Dr. Carpenter's diagram on p. 188, and let No. 11 be the card known to Mr. Bishop, and which is to be finally discovered by Dr. Carpenter. "Drop your left hand on any row you wish *taken away*," says Mr. Bishop to Dr. Carpenter. Suppose, *by chance*, B, D, and A successively dropped on and removed, as in the instance given by Dr. Carpenter, then the upper pair of row C, then 15, we have 11 left and the trick done.

Suppos that C is selected first. Mr. Bishop may now assure Dr. Carpenter that the card wanted is in that row, and that he has forced Dr. Carpenter to select it. The chances are equal that Dr. Carpenter will in his next selection drop on that pair in row C, which includes 11. Should Dr. Carpenter in his third choice drop on 11, a most convincing proof of Mr. Bishop's will-compelling power will have been exhibited.

Should Dr. Carpenter however drop on 15, Mr. Bishop has merely to ask him to put it aside, and turning up the remaining card to exhibit it as the chosen and identified card. By a combination of the two methods of removing and leaving, Mr. Bishop can provide for all cases, and can perform a trick well known to schoolboys.

Dr. Carpenter, as I read his letter, tells us how Mr. Bishop acted when he himself was the subject of the experiment. If Dr. Carpenter can declare that the rows of cards, pairs of cards, and single cards *dropped in* were *in all three experiments* removed, I must confess that the laws of probabilities are against me, and that there seems to be strong proof of Mr. Bishop's power of *will-compelling*, a power which, as far as I have heard, Mr. Bishop has not yet publicly claimed to possess.

If Mr. Bishop *did not* know where the selected card was placed, Dr. Carpenter must invent a name for Mr. Bishop's new power of discovering a card, the position of which neither Mr. Bishop nor "the subject of the experiment" knew.

We can all regret with Dr. Carpenter "that Mr. Bishop did not offer for like careful testing experiments," &c.

I had the pleasure of attending a *public* performance given by Mr. Bishop in Edinburgh, on which occasion Mr. Bishop, much to the entertainment of a crowded hall, exhibited the legerdemain by which he had duped the subjects of, I believe, the before-mentioned experiments.

At this entertainment Mr. Bishop also showed how spiritualists performed such feats as knocking nails into boards, putting rings on scarves, &c., while their hands were tied together behind their backs and secured to a post. Prof. Turner, of the University of Edinburgh, explained to the spectators (no doubt at Mr. Bishop's request) that Mr. Bishop *seemed* to be enabled to perform those feats by the peculiar conformation of the bones and muscles—perhaps both—of his shoulder and arm.

We are told by newspaper correspondents that to this physical gift Mr. Bishop has added the power of reading and getting pictures of his subjects' thoughts, and now Dr. Carpenter endows him with the power of controlling the wills of his subjects, or—"*may*" teste—with some unnamed power still more mysterious. To Mr. Bishop as the successor of the Westminster whale or of Master Pongo, no one can have the slightest objection. Mr. Bishop as a *great* scientific phenomenon will, I fear, require better backing than the *careful testing* of Dr. Carpenter, and letters of introduction from scientific and medical men in Edinburgh who received Mr. Bishop, and in their turn gave him letters of introduction as a clever conjuror who performed by mechanical means feats of strength and agility attributed by spiritualists to their immaterial familiars.

THOMSON WHYTE

Merchiston Castle School, Edinburgh, July 2

Mind-Reading versus Muscle-Reading

SEVERAL years ago I had the opportunity of witnessing in a private circle of friends some experiments on so-called "thought-reading," even more striking than those recently described in your columns and elsewhere. An attentive observation of these experiments led me to question the accuracy of that explanation of the phenomenon with which Dr. Carpenter has made us so familiar, namely, unconscious muscular action on the one side, and unconscious muscular discernment on the other. After making the most extravagant allowances for the existence in some persons of a muscular sense of preternatural acuteness, here still remained a large residuum of facts wholly unaccounted for on any received hypothesis. These facts pointed in the direction of the existence either of a hitherto unrecognised sensory organ, or of the direct action of mind on mind without the intervention of any sense impressions. Such startling conclusions could not be accepted without prolonged and severe examination, and it was solely in the hope of stimulating inquiry among those who had more leisure and more fitness for the pursuit than myself that I published the brief record of my experiments which, some years ago, brought derision and denunciation upon me. As no physiologist came forward to give the subject the wide and patient inquiry it demanded, I went on with the investigation, and for five years have let no opportunity slip which would add to the information I possessed. A letter addressed to the *Times*, asking for communications from those who had witnessed good illustrations of the "willing game," brought me in, at the time referred to, a flood of replies from all parts of England, and down to the present time fresh cases are continually coming under my notice. Each case that seemed worthy of inquiry was, if possible, visited and investigated either by myself during the vacation, or by a friend on whom I could rely. It is true that many long journeys have been taken and much time has been spent without a commensurate reward, but this was to be expected. Still, after casting out cases which might or might not have been due to "muscle-reading," there remained abundant evidence to confirm my belief in the insufficiency of Dr. Carpenter's explanation. Until this evidence is published, which it will shortly be, and the accessible cases are examined and reported upon by a competent and impartial committee, I simply ask the public to suspend their judgment on this question. And to show that this is not an unreasonable request on my part, I here give a few particulars of a remarkable case which reached me only a few months ago, and was carefully investigated by myself last Easter.

A clergyman in Derbyshire has five young children, four girls and one boy, aged from nine to fourteen years, all of whom are able to go through the ordinary performances of the "willing game" rapidly and successfully, *without the contact of the hand, or of any communication besides the air between the person operating and the subject operated on*. More than this, letters and words, or names of places, of persons, and of cards, can be guessed with promptness and accuracy; the failures in any examination not amounting to one in ten consecutive trials. The failures, I am assured by the father—and there is no reason to doubt his veracity—form a far smaller fraction when the children are not embarrassed by the presence of strangers; for example, the parents assured me that their children, before I arrived, told correctly seventeen cards chosen at random from a pack, without a single failure, and after that correctly gave the names of a dozen English towns indiscriminately selected. I will however only ask attention to what came under my own observation, which in brief was as follows:—

One of the children, Maud, a child of twelve, was taken to an adjoining room, and both the doors between fastened. I then wrote on paper the name of some object *not in the room* (to prevent unconscious guidance by the *eyes* of those who knew the thing selected), and handed this paper round to those who were present. Not a word was allowed to be spoken. I myself then recalled the child, placed her with her back to the company, or sometimes blindfolded her before bringing her into the room, and put her in a position where no whisper or other private communication could reach her undetected. In from two to twenty seconds she either named the object I had written down (the paper, of course, being concealed) or fetched it, if she could do so without difficulty. Each child was tried in succession, and all were more or less successful, but some were singularly and almost invariably correct in their divination of what I had written down; what was more curious, the maid-servant was equally sensitive. This led me to try other experiments with those who knew the words chosen: and the father was found to be pre-eminently the best willer, and to be in fact almost as necessary for success as the sensitive "guesser"; further experiments showed that a battery of minds, all intently fixed on the same word, was far more successful than one or two alone. Apparently a *nervous induction* of the dominant idea in our minds took place on the passive mind of the child, and the experiments recalled the somewhat analogous phenomena of electric and magnetic induction. There seemed to be a veritable exoneural action of the mind.

I am quite prepared for the chorus of sceptical laughter which will greet this statement. That there should be disbelief is quite natural; a desire for further inquiry is all I ask for. To those who, with a single eye for truth, even if it be in collision with received opinions, are anxious to know if every possibility of error or deception was removed, permit me to add the following additional experiments. Instead of allowing the child to return to the drawing-room, I told it to fetch the object as soon as it "guessed" what it was, and *then* return with it to the drawing-room. Having fastened the doors I wrote down the following articles one by one with the results stated: *hair-brush*, correctly brought; *orange*, correctly brought; *wine-glass*, correctly brought; *apple*, correctly brought; *toasting-fork*, wrong on the first attempt, right on the second; *knife*, correctly brought: *smoothing-iron*, correctly brought; *tumbler*, correctly brought; *cup*, correctly brought; *saucer*, failure. On being told this object the child said, "Saucer came into my head, but I thought you would never ask for that after asking for a cup, so I wasn't sure what it was." Then names of towns were fixed on, the name to be called out by the child outside the closed door of the drawing-room, but guessed when fastened into the adjoining room. In this way Liverpool, Stockport, Lancaster, York, Manchester, Macclesfield were all correctly given; Leicester was said to be Chester; Windsor, Birmingham, and Canterbury were failures. I might give many other similar trials, for I spent three long evenings testing the children; but these results and the attempts made to answer the many questions that at once started to the mind, such as the effect of distance, &c., must be left for the present. Meanwhile, at the suggestion of Mr. Romanes, I have arranged for a small committee of scientific experts to visit the family, and verify or disprove the conclusion to which I have arrived, which is certainly opposed to that drawn by Mr. Romanes from his experiments on Mr. Bishop (NATURE, vol. xxiv. p. 172). Whether Dr. Carpenter will find in this case "a precise confirmation" of everything he has said on the subject I cannot say.

W. F. BARRETT

July 3

A Case of Slow, Sub-Tropical Discharge of Earth-Electricity, and the Sun Recognisant thereof

IN the course of yesterday afternoon, in the midst of a sky otherwise clear and exquisitely blue, a large cloud of unusual shape and character began to form in the upper regions of the atmosphere vertically over, but very far above, the southern slope and even most elevated mountain tops of Madeira, and remaining there, as it did, most fixedly more than half the day, so contrary to the locomotive habits of ordinary clouds, it soon attracted the attention, and presently the fears, of most of the inhabitants.

As seen from this place, between 1h. and 3h. p.m., there was little more than a single dense cloud of peculiarly rounded outline and somewhat elliptical figure, stretching from the western horizon to within 10° or 15° of the zenith; but as time advanced,

other and successively smaller clouds were formed directly under the first, having symmetrical and concentric outlines therewith, while the central vertical axis, which might be conceived as passing through the whole series, remained unchanged and fixed in space. This central fixity, too, of them all continued, together with the infinite smoothness of the outlines of all the smaller lower strata of cloud, although the largest and uppermost one visible to us began to put forth a variety of fringes of cirro-cumulous character; and, as tested by the spectroscope before sunset, all the lower smooth-rimmed clouds were remarkable for the large quantity of watery vapour they contained, and held fast too, for no rain fell. As sunset approached every one was gazing at the strange phenomenon of a cloud-congeries of most portentous size and absolute fixature above the trade-wind, probably also the anti-trade region; and after sunset the most gorgeous coloured illuminations through all the ranges of scarlet-red, red, crimson-red, ultra-red, and then dun-coloured and grey passed from member to member of the series, distinguishing the various heights of its strata one above the other; while the greatness of the general height was shown, even long after darkness had set in, by a faint lunar-like illumination of the northern outline of the whole. But by ten o'clock that began to fail, and the system of superposed clouds was beginning to contract on its central axis, and faded away, without leaving its place, before morning.

In so far we had been witnessing, though without any positive light of its own, a vertical series of disks of cloudy matter, extremely like the lower end of the successive, transverse, discous arrangements seen in a gas vacuum-tube of large dimensions, when the electric discharge from a powerful induction-coil is passing through it; and we were inevitably reminded thereby that the cosmical electric theory of M. Gaston Planté (of "secondary batteries or storage" fame) justifies an escape of the earth's interior electricity from time to time into planetary space, and more particularly to the sun.

Was there, however, in this case any symptom of the sun exciting, or calling for, any such discharge, and from this part of the earth?

The sun was undoubtedly in the Northern Tropic, and the highest northern declination for the year had just been reached; but for a fortnight or more past the solar spot manifestations had generally been weak, almost fading away. This I knew well, having taken a picture of the sun-spots every day (Sundays excepted) since I have been here. However, though the appearances were as poor as they well could be on June 21, 22, and 23, yet on Friday, June 24, there was a little improvement, some new, though small symptoms appearing in either solar tropic. On Saturday, June 25, these new features were confirmed and slightly increased. But what were they on Sunday, June 26, when the extraordinary cloud-arrangement was hanging so long above Madeira?

I, who am here merely as a private amateur in a different subject, know not; but on Monday morning, so early as 5h. 30m. a.m., I was astonished and delighted at the solar scene then presented. The spots first caught sight of on Friday were now well advanced and much developed; a new group with extensive double ramifications had also appeared in the same tropic nearer the equator; while finally, near the middle of the sun's disk in the south tropic, were two large spots, with connections extending over 60,000 miles in length of solar surface, and indicating more solar energy to have been thereby rapidly, if not suddenly, manifested within the last forty hours, than anything which I, at least, have witnessed for a very long time past.

Carbonic Acid Gas not Free in Sea Water

IN a short paragraph in NATURE, vol. xxiv. p. 176, it is stated that Tornö, in the Norwegian Deep-Sea Expedition, had found "carbonic acid both in a gaseous and basic form."

For some time past I have doubted whether there was any free carbonic acid gas in the deep water where pressure should make its presence felt. Lately, in a paper to the Royal Microscopical Society, I have demonstrated that if there is any carbonic acid in the sea water at great depths, its dissolving action is not equal in rapidity and intensity to that exercised by a microscopic Thallophyte which bores into and dissolves sponge spicules from within. Moreover amongst deep sea deposits I find perfect organisms which have long been dead, which have been penetrated by parasites and covered here and there by foraminifera, and yet in exposed parts, the ornamentation is perfect. There is no evidence of erosion.

Now on carefully examining into Tornö's essay come to a different conclusion to the writer in NATURE, and I find that the able Scandinavian denies the existence of free carbonic acid in the sea.

The following notes, which I made in abstracting Tornö's "Chemi" of the Norwegian North Atlantic Expedition, Part II., may be interesting:—

The carbonic acid gas, driven off by the process of boiling sea water, when collected, varied in a most marked manner; it was always appreciable, and the quantity was sometimes large. The pressure was that of the atmosphere. Under different conditions, and when the gases were boiled out in a vacuum created by steam, and of course at a lower temperature, the quantity of carbonic acid gas was often *immeasurably small*. Moreover the quantity varied.

Jacobsen, by distillation, succeeded in expelling the whole amount of carbonic acid contained in a quarter litre of sea water, and found that North Sea water contained 100 mgr. per litre. The neutral carbonates in the residuary deposit contained about 10 mgr. per litre. Hence a very small proportion of the carbonic acid driven off by distillation, could have been present in bicarbonates. Vierthaler had asserted that the carbonic acid in sea water was got out of the bicarbonates by boiling.

If the carbonic acid is free and absorbed by the sea water in a free gaseous form, it is remarkable that it should not be more readily got. Jacobsen supposed that sea water has a peculiar property of retaining its carbonic acid, owing to the presence of the chloride of magnesia. Buchanan was led to believe that most of the salts were in some degree distinguished by the property of determining the retention of carbonic acid in the sea. He especially insisted on the importance of the sulphates, and asserted the mean amount of carbonic acid present in the waters of the Southern Seas to be 43·25 mgr. per litre.

Tornö, following Jacobsen, found the amount of carbonic acid gas present in the water of the track of the northern cruise of 1877 to be about 100 mgr. a litre, but got 12 mgr. per litre as a variation in the amount.

He was struck with the improbability that sea water should possess so remarkable a power of retaining mechanically one gas and exert no corresponding influence on others, and then he found that sea water had *an alkaline reaction*. He began to believe that some of the neutral carbonates had been decomposed during the boiling, and had evolved much of the carbonic acid gas.

He then proved by experiment that the saline mixture in sea water, on the temperature being raised to the boiling point, decomposed neutral carbonates, and that all previous experiments with the object of measuring the carbonic acid in the sea water had been faulty. He was influenced by some experiments on the determination of carbonic acid gas in mineral water, and applied the method to sea water.

He found the total amount of carbonic acid gas in a specimen to be 97 mgr. per litre, and the proportion forming neutral carbonates to average about 53 mgr. The difference, 44 mgr., cannot occur free as gas, but will unite with the carbonates to form bicarbonates. Hence Jacobsen's experiments could be explained on the assumption that sea water contains no trace of free carbonic acid, but as much as 53 mgr. per litre forming carbonates, and only 44 mgr. forming bicarbonates.

On page 35 he states: "*If we bear in mind that sea water is an alkaline fluid which does not contain the smallest trace of free carbonic acid.*"

What a comfort this must be to globigerina and coral reefs!

Symbolical Logic

I AM afraid I share the proverbial obtuseness of my countrymen in the matter of jokes. I really did not at first see the point of Mr. Venn's humorous suggestion that "an attitude of slight social repression" should be observed towards troublesome authors of new proposals. Now however that Mr. Venn has kindly pointed it out to me (see NATURE, vol. xxiv. p. 140), I see the joke perfectly and can laugh at it heartily.

As for the little parenthesis which offended me, I am sorry I noticed it, and hope Mr. Venn will forgive the passing irritation which it produced. What he means by the words "I knew that he was very anxious that the fact should be known," I do not quite understand; but the matter is too unimportant for further comment.

With regard to the "crowning triumph" quotation or misquotation, I can only congratulate Mr. Venn on the adroitness with which he eluded the dilemma in which I quite thought I should place him. In my simplicity I expected that he would answer *Yes* or *No* to my question; but Mr. Venn was not thus to be caught.

It is but fair to own that the critical remarks which I made on Mr. Venn's book in my last letter, though perfectly just as far as they go, are somewhat one-sided. As I only spoke of points on which he and I differ in opinion it could not well be otherwise. His book contains much other matter which I did not touch upon at all, and of which I entertain a very high opinion. His diagrammatic method especially is most ingenious, and his exposition of it is lucid and attractive. The limits of its application in actual practice are, as he himself points out, rather narrow; but within those limits, and for purposes of illustration and verification, it is undoubtedly an important contribution to the science of logic.

Boulogne-sur-Mer, July 2

How to Prevent Drowning

THOSE who have followed the correspondence commenced in NATURE by Dr. MacCormac may be interested in the following extract from an essay, "Pourquoi les Bêtes nagent naturellement," which occurs oddly enough in a book entitled "Observations sur les Plantes et leur Analogie avec les Insectes," published at Strasburg in 1741 by Guido Augustin Bazin, a physician of that place:—

"Lorsqu'un homme qui n'a point appris à nager tombe dans l'eau, il n'y a point de doute que s'il pouvoit tenir son corps dans une position verticale et fixe, et porter ses jambes en avant, comme il fait lorsqu'il marche sur la terre, il ne pût nager naturellement aussi bien que, les bêtes, les habiles nageurs le font souvent pour leur plaisir. Nous connoissons un peuple entier qui ne nage pas autrement, ce sont les Hottentots; voici ce qu'en dit Mr. Kolbe, dans une bonne description qu'il nous a donnée du Cap de bonne Espérance:—'Aussi faut-il avouer qu'ils (les Hottentots) sont les meilleurs et les plus hardis nageurs que j'aye jamais vû. Leur manière de nager a même quelque chose de frappant, et je ne sçache pas qu'aucune nation s'y prenne de la même façon. Ils nagent tout droits; leur col est entièrement hors de l'eau, aussi bien que leurs bras, qu'ils étendent en haut; ils se servent des pieds pour avancer, et pour se mettre en équilibre, mais je n'ai jamais pu sçavoir comment ils les font jouer. Tout ce qu'il y'a de sûr, c'est qu'ils avancent très vite. Ils regardent en bas, et ont presque la même attitude que s'ils marchoient sur terre ferme.' Mais cette attitude est impossible à un homme qui ne s'est pas point exercé à la prendre, parce que les mouvements de l'eau, et l'incertitude de son corps, toujours vacillant dans un liquide, le tirent à tout moment de la direction verticale, et l'entraînent malgré lui en avant ou en arrière" (pp. 44, 45).

W. T. THISELTON DYER

Resonance of the Mouth Cavity

I HAVE not tried Mr. Naylor's experiment, but from the account which he gave of it I could not see that any novel fact was involved, nor do I now see that the fact of "the different rates of vibration being *already in the air*" alters materially the conditions of the case. Whether the sounds are produced by the clatter of wheels, the impact of the thumb-nail upon the teeth, or by the vibrating tongue of a jew's-harp, the part played by the mouth-cavity in selecting the notes of a tune is substantially the same.

GEORGE J. ROMANES

Storage of Energy

LIKE many others, I have given much thought to the accumulation of force, and have felt much astonished at the account of Faure's battery, if it is to be so called, although of course such a development was to be expected from the time that Planté made his.

I see that men immediately rush to waterfalls, rivers, and tides to obtain the power for accumulation when they leave coal and wood; my ideas are rather in the direction of wind; and I have often pictured our country covered, like that around Zaandam, with windmills. The wind is not constant, but more so than most of our efficient streams, and it is found at every spot. The power is quite unlimited, and we can moderate the action of the machinery whenever we obtain the requisite force. Storage has hitherto been required. I have imagined our windmills pumping up water to great reservoirs, but we have not yet learned to make reservoirs for water except at an enormous expense and in unprotected valleys; other imaginings have come into many minds, but if we have a really true and safe storage, such as described, the wind will become our fire to warm us, our steam to drive us, our gas to light us, and our universal servant. The wind will drive our mills, too (except when a fog comes, lasting so long that our stores of power fail), with sufficient storage, inconstancy will cease to trouble us, whilst every valley may have its lights and every mountain-top its beacon, and darkness will scarcely trouble mankind in this new-coming world of light. We have heard of the golden servants of Vulcan and the mechanical slaves of the great Khan. What will be the result when every man has the wind at his command and the lightning at his service by friction, like Aladdin? It seems to me that the wind is the great power that we shall next use, and that Prince—the power of the air—shall be bound to serve us for at least a thousand years.

The Dutch have long made windmills, but when over in Holland a few years ago examining a little, I was unable to find the books wanted on the subject.

The fact that coal can be carried will not affect the question if wind is used. Wind carries itself. We shall seek our power from the heavens instead of the infernal pits, and a race of healthy, ruddy faces will take the place of the blackened and degraded countenances from mines.

I wish to show that we have excess of power in the wind. Will this new accumulator, of which I know nothing from personal experience, serve us to keep it? To keep it a few hours is a great point. Coal becomes secondary if we accumulate the force of the wind, and Niagara itself will be no longer wanted. Of course we need machines to use the wind-power. At present coals are cheaper with us; not so in all parts of Holland, and not so in many other places. However, here we have problems enough to solve; do not let us throw cold water on the discoveries of others, or show, as scientific men so often do, our own opinion to be dear beyond the truth among others.

R. A. S.

Explanation of the Female Dimorphism of Paltostoma torrentium

IN his paper on "*Paltostoma torrentium*, eine Mücke mit zweigestaltigen Weibchen" (*Kosmos*, vol. viii. pp. 37–42), my brother Fritz Müller supposes that this species of Blepharoceridæ originally was blood-sucking, but in later times changed its habits and became fond of flower-nectar. In the males, who need only little food, this change of habits and the corresponding change of the mouth-parts was accomplished, my brother supposes, more rapidly and perfectly than in the females, who, maturing eggs and passing the winter, stand in need of more albuminous food than the males do. Whilst therefore in some females of *Paltostoma torrentium* the same change of habits and mouth-parts has taken place as in the males, other females have still more or less continued their original blood-sucking habits and preserved their original blood-sucking instruments.

This explanation given by my brother is not yet proved by any direct observation of *Paltostoma's* habits. He mentions, as an indirect argument for his opinion, that in several Diptera the females have been stated to be blood-sucking, whilst the males take nectar of flowers. It may therefore be worth publishing, that in *Empis punctata* really just the same takes place as my brother's explanation of the female dimorphism in *Paltostoma torrentium* requires to be supposed: males who exclusively feed on flower nectar, besides females, both enjoying flower-honey and attacking living animals and sucking their blood. Several weeks ago (May 26) a great many males as well as females of *Empis punctata* roved on the flowers of hawthorn (*Cratægus exyacantha*). The males were exclusively occupied with sucking nectar. Of the females some did the same, whilst others attacked, murdered, and consumed the most clever visitor of flowers among all our Syrphidæ, *Rhingia rostrata*.

HERMANN MÜLLER

ACROSS AFRICA[1]

TO cross Africa has almost ceased to be an extraordinary feat. Indeed it seems evident, the more we know of the Portuguese native traders, that even before Livingstone's memorable first journey, it was no uncommon thing for the Pombeiros to do in the ordinary way of business. Of course some routes are more dangerous than others, and that by which Stanley made his famous march was perhaps the most difficult and dangerous that could be selected. Still the journey performed by Major Serpa Pinto was in many ways remarkable, and perhaps not its least remarkable feature is the characteristic manner in which he tells his story. The Major's narrative is in every respect a contrast to the quiet and sober narrative of Dr. Holub, recently reviewed in these pages. The Major is all excitement and enthusiasm, and his frequent digression to unbosom himself of his feelings under his frequently trying circumstances, though they do not convey much information, are pleasant reading. The expedition of which he was leader was fitted out very handsomely by the Portuguese Government, its object being to cross the continent from the Portuguese settlements in the west to those on the east coast. He was accompanied by MM. Ivens and Capello, but these soon parted from him, and conducted an exploration on their own account, the full narrative of which has yet to be published. Much time was wasted at the outset before the expedition could leave Benguella, collecting carriers and making other arrangements, so that it was January, 1878, before the Major fairly started for the interior. Although much of the ground he traversed had been gone over before, coinciding partly with the route of Livingstone, still he was able to open up a considerable stretch of new country, and most of all to clear up to a great extent the complicated hydrography of the region lying between the West Coast and the Zambesi. While the Major has many interesting notes on the natural history of the country he traversed, and while he seems to have been able to bring to light some new animals and not a few new plants, the main value of his narrative lies in the full details he gives on the geography and ethnology of Western South Africa. He was unable to carry out the original programme of the expedition, having been compelled to turn southwards on reaching the Central Zambesi, reaching the East Coast at Natal. On leaving Benguella the Major proceeded in a south-easterly direction towards the Cunene, before reaching which he turned north-eastwards, proceeding by Caconda to Bihé. After staying here for some time he again turned south-eastwards across the Cuando to the Zambesi, a little below its junction with the Liba, which seems to have more right to be considered the main stream than that which comes from the east. Proceeding down the Zambesi, passing numerous cataracts, he got into trouble among the Barotse, a new king having succeeded to the deposed Sepopo, whom Dr. Holub found ruling the Marutse-Mabunda kingdom at Sesheke. Escaping with bare life, he fell in with the French missionary family Coillard, who gave him all possible succour, visited and attempted to survey the Victoria Falls, and proceeded southwards and eastwards in a leisurely way into country pretty well known, but of which and of its various native states he is able to give us some interesting details. Between the West Coast and the Zambesi the expedition must have crossed hundreds of rivers, many of which Major Pinto has laid down with approximate accuracy in his maps. For he deserves the highest praise for the persistency with which he took his observations under the most trying circumstances, so that to the cartographer his work is of the greatest value. It is no easy matter to discriminate the various watersheds here, and indeed the observations of Major Pinto, combined with those of previous travellers, shows that many of the rivers which flow north to the Congo, south-west to the Atlantic, south by Cubango to Lake Ngami, and south-east to the Zambesi, rise quite close together on what is really a table-land; and in the rainy season it will often be difficult for them to make up their minds which direction they shall take. Major Pinto's numerous maps tend greatly to clear up the complicated hydrography of this region.

The country through which he passed to reach the Zambesi is varied in its aspect and productiveness, though most of it is luxuriantly fertile, and capable of great development. Much of it is however swampy, and even cultivated fertile districts are depopulated, mainly through wars and slave-hunting. Major Pinto tells us much that is interesting on the metal-working, which is common along the first part of his route. There seems to be really a large store of iron in this region, and the natives show considerable ingenuity in working it. There are several chief centres for these operations, and the metal is fashioned into all sorts of implements and weapons.

FIG. 1.—Cabango Man.

"During the coldest months, that is to say June and July, the Gonzellos miners leave their homes and take up their abode in extensive encampments near the iron-mines, which are abundant in the country. In order to extract the ore they dig circular holes or shafts of about ten to thirteen feet in diameter, but not more than six or seven feet deep; this arises most probably from their want of means to raise the ore to a greater elevation. I examined several of these shafts in the neighbourhood of the Cubango, and found them all of a similar character. As soon as they have extracted sufficient ore for the work of the year they begin separating the iron. This is done in holes of no great depth, the ore being mixed with charcoal, and the temperature being raised by means of primitive bellows, consisting of two wooden cylinders about a foot in diameter, hollowed out to a depth of four inches, and covered with two tanned goat-skins, to which are fixed two handles, twenty inches long and half an inch thick. By a rapid movement of these handles a current of air is produced which plays upon the charcoal through two hollow wooden tubes attached to the

[1] "How I Crossed Africa, from the Atlantic to the Indian Ocean," &c. By Major Serpa Pinto. Translated from the Author's manuscript by Alfred Elwes. Two vols. Maps and Illustrations. (London: Sampson Low and Co., 1881.)

cylinders, and furnished with clay muzzles. By incessant labour, kept up night and day, the whole of the metal becomes transformed, by ordinary processes, into spades, axes, war-hatchets, arrow-heads, assegais, nails, knives, and bullets for fire-arms, and even occasionally fire-arms themselves, the iron being tempered with ox-grease and salt. I have seen a good many of these guns carry as well as the best pieces made of cast steel."

The book contains several illustrations of the methods adopted, and the double-bellows used for the furnace is very curious. His observations on the animals met with along his route are valuable, and he has carefully indicated on his map where the principal animals are found. Elephants seem to be abundant enough south-east of Bihé, and lions were met with in considerable numbers as the Zambesi was approached. He also met with the huge and dangerous buffaloes familiar to readers of Livingstone's First Journey. One of our illustrations gives a good idea of an antelope which was met with in the Cuchibi, which the Major thus describes :—

"At one of the turns of the river I perceived three antelopes of an unknown species, at least to me; but just as I was in the act of letting fly at them they leaped into the water and disappeared beneath its surface. The circumstance caused me immense surprise, which was increased as I went further on, as I occasionally came across several of these creatures, swimming, and then rapidly diving, keeping their heads under water, so that only the tips of their horns were visible. This strange animal, which I afterwards found an opportunity of shooting on the Cuchibi, and of whose habits I had by that time acquired some knowledge, is of sufficient interest to induce me for a moment to suspend my narrative to say a few words concerning it. It bears among the Bihenos the name of Quichôbo, and among the Ambuellas that of Buzi. Its size, when full grown, is that of a one-year-old steer. The colour of the hair is dark grey, from one quarter to half an inch long, and extremely smooth; the hair is shorter on the head, and a white stripe crosses the top of the nostrils. The length of the horns is about two feet, the section at the base being semicircular, with an almost rectilinear chord. This section is retained up to about three-fourths of their height, after which they become almost circular to the tips. The mean axis of the horns is straight, and they form a slight angle between them. They are twisted around the axis without losing their rectilinear shape, and terminate in a broad spiral. The feet are furnished with long hoofs similar to those of a sheep, and are curved at the points. This arrangement of its feet and its sedentary habits render this remarkable ruminant unfitted for running. Its life is therefore in a great measure passed in the water, it never straying far from the river banks, on to which it crawls for pasture, and then chiefly in the night-time. It sleeps and reposes in the water. Its diving-powers are equal, if not superior, to those of the hippopotamus. During sleep it comes near to the surface of the water, so as to show half its horns above it. It is very timid by nature, and plunges to the bottom of the river at the slightest symptom of danger. It can easily be captured and killed, so that the natives hunt it successfully, turning to account its magnificent skin and feeding off its carcase, which is however but poor meat. Upon leaving the water for pasture its little skill in running allows the natives to take it alive; and it is not dangerous, even at bay, like most of the antelope tribe. The female, as well as the male, is furnished with horns. There are many points of contact between the life of this strange ruminant and that of the hippopotamus, its near neighbour. The rivers Cubangui, Cuchibi, and the upper Cuando offer a refuge to thousands of Quichôbos, whilst they do not appear either in the lower Cuando or the Zambesi. I explain this fact by the greater ferocity of the crocodiles in the Zambesi and lower Cuando, which would make short work of so defenceless an animal if it ventured to show itself in their waters."

Major Pinto's account of the powerful kingdom of Bihé is full of interest. It is evident from his narrative and those of Dr. Holub and Mr. Joseph Thomson that these African states are in a constant state of unstable equilibrium. Not only are the chiefs and dynasties frequently changed, but an entire population may be removed or reduced to slavery, and its dominant place taken by a conquering people. The Bihenos are probably the most extensive travellers in Africa.

"Where travelling is concerned as connected with trade, nothing comes amiss to the Bihenos, who seem ready for anything. If they only had the power of telling where they had been and describing what they had seen, the geographers of Europe would not have occasion to leave blank great part of the map of South Central Africa. The Biheno quits his home with the utmost indifference, and bearing a load of sixty-six pounds of goods, will start for the interior, where he will remain two, three, and four years; and on his return, after that lapse of time, will be received just as though he had been on a journey of as many days. Silva Porto, whilst engaged in doing business with the Zambesi, was despatching his negroes in other directions, and was trading at the same time in the Mucusso country and in the Lunda and Luapula territories. The fame of the Bihenos has travelled far and wide, and when Graça attempted his journey to the Matianvo he first proceeded to the Bihé to procure carriers. These people have a certain emulation among one another as travellers, and I met with many who prided themselves on having gone where no others had ever been, and which they called *discovering new lands*. They are brought up to wandering from their very infancy, and all caravans carry innumerable children, who, with loads proportionate to their strength, accompany their parents or relatives on the longest journeys; hence it is no uncommon thing to find a young fellow of five-and-twenty who has travelled in the Matianvo, Niangué, Luapula, Zambesi, and Mucusso districts, having commenced his perigrinations at the age of nine years."

Major Pinto has a good deal to tell us of the various kinds of ants he met with on his journey, though the value of his observations is much decreased from his want of a knowledge of entomology. Here is his account of one terrible insect :—

"When the work of cutting down the wood for our encampment commenced I saw a sudden commotion among my blacks, who then took to their heels in every direction. Not understanding the cause of their panic, I immediately proceeded to the spot to make inquiries. On the very place which I had selected for my camp appeared issuing from the earth millions of that terrible ant called by the Bihenos *quissonde*, and it was the sight of these formidable creatures which scattered my men. The quissonde ant is one of the most redoubtable *wild beasts* of the African continent. The natives say it will even attack and kill an elephant, by swarming into his trunk and ears. It is an enemy which, from its countless numbers, it is quite vain to attack, and the only safety is to be found in flight. The length of the quissonde is about the eighth of an inch; its colour is a light chestnut, which glistens in the sun. The mandibles of this fierce hymenopter are of great strength, and utterly disproportioned to the size of the trunk. It bites severely, and little streams of blood issue from the wounds it makes. The chiefs of these terrible warriors lead their compact phalanxes to great distances and attack any animal they find upon the way. On more than one occasion during my journey I had to flee from the presence of these dreadful insects. Occasionally upon my road I have seen hundreds of them, apparently crushed beneath the foot, get up and continue their march, at first somewhat slowly,

but after a time with their customary speed, so great is their vitality."

The author gives some valuable details concerning the Mucassequeres, who seem to be a remnant of one of the primitive African tribes.

"The Mucassequeres occupy, jointly with the Am-

Fig. 2.—The Quichôbo.

buellas, the territory lying between the Cubango and Cuando, the latter dwelling on the rivers and the former in the forests; in describing the two tribes, one may say that the latter are barbarians and the former downright savages. They hold but little communication with each other, but, on the other hand, they do not break out into hostilities. When pressed by hunger the Mucassequeres will come over to the Ambuellas and procure food by the barter of ivory and wax. Each tribe would seem to be independent, and not recognise any common chief. If they do not fight with their neighbours they nevertheless quarrel among themselves; and the prisoners taken in these conflicts are sold as slaves to the Ambuellas, who subsequently dispose of them to the Bihé caravans. The Mucassequeres may be styled the true savages of South Tropical Africa. They construct no dwelling-houses or anything in the likeness of them. They are born under the shadow of a forest-tree, and so they are content to die. They despise alike the rains which deluge the earth and the sun which burns it; and bear the rigours of the seasons with the same stoicism as the wild beasts. In some respects they would seem to be even below the wild denizens of the jungle, for the lion and tiger have at least a cave or den in which they seek shelter, whilst the Mucassequeres have neither. As they never cultivate the ground, implements of agriculture are entirely unknown among them; roots, honey, and the animals caught in the chase constitute their food, and each tribe devotes its entire time to hunting for roots, honey and game. They rarely sleep to-day where they lay down yesterday. The arrow is their only weapon; but so dexterous are they in its use, that an animal sighted is as good as bagged. Even the elephant not unfrequently falls a prey to these dexterous hunters, whose arrows find

Fig. 3.—Malanca.

every vulnerable point in his otherwise impervious hide. The two races which inhabit this country are as different

in personal appearance as they are in habits. The Ambuella, for instance, is a black of the type of the Caucasian race; the Mucassequere is a white of the type of the Hottentot race in all its hideousness. Many of our sailors, browned by the sun and beaten by the winds of many a storm, are darker than the Mucassequeres, whose complexion besides has so much of dirty yellow in it as to make the ugliness more repulsive. I regret exceedingly my inability to obtain more precise data concerning this curious race, which I consider to be worthy the special attention of anthropologists and ethnographers. In my opinion this branch of the Ethiopic race may be classified in the group of the Hottentot division. In form it possesses many of the characteristics of the latter, and we may observe in this peculiar race a sensible variation in the colour of the skin. The *Bushmen* to the south of the Calaári are very fair of hue, and I have noticed some who were almost white. They are low of stature and thin of body, but exhibit all the characteristics of the Hottentot type. To the north of that same desert tract, more especially about the salt-lakes, there is another nomad race, that of the Massaruas, strongly built, of lofty stature, and of a deep black, who possess the same Hottentot type, and who indubitably belong to the same group. I was told on the Cuchibi that between the Cubango and the Cuando, but a good deal to the south, there existed another race, in every respect similar to the Mucassequeres, both in type and habits, but of a deep black colour. In consideration therefore of the affinity of character, I have no hesitation in admitting that the Hottentot group of the Ethiopic race extends to the north of the Cape as far as the country lying between the Cubango and the Cuando, passing through sundry modifications of colour and stature, due probably to the conditions under which they live, to altitude, to the great difference of latitude, or even to other causes that are less apparent."

By the time Major Pinto reached the Barotse territory and fell in with the hospitable missionary family Coillard, he had got on to comparatively well-known ground, though the interest of his story is sustained to the very end; and even here he succeeds in adding something to our knowledge of the countries through which he passed. His visit to the Great Falls of the Zambesi, and his illustrations taken from various points, are a material addition to what we know of them from the narratives of Livingstone and Mohr. Some of his observations are worth quoting, especially as, under circumstances of the greatest danger, he succeeded in making a fairly accurate survey. "Mozi-oa-tunia" is a Basuto word, meaning "the smoke is rising," "so that it is very easy to suppose how a name, common among the natives and apparently so apt and appropriate, came to be given by strangers to the cataract itself.

"*Mozi-oa-tunia* is neither more nor less than a long trough, a gigantic crevasse, the sort of chasm for which was invented the word abyss—an abyss profound and monstrous into which the Zambesi precipitates itself bodily to an extent of 1978 yards. The cleft in the basaltic rocks which form the northern wall of the abyss is perfectly traceable, running east and west. Parallel thereto, another enormous wall of basalt, standing upon the same level, and 110 yards distant from it, forms the opposite side of the crevasse. The feet of these huge moles of black basalt form a channel through which the river rushes after its fall, a channel which is certainly much narrower than the upper aperture, but whose width it is impossible to measure. In the southern wall, and about three-fifth parts along it, the rock has been riven asunder, and forms another gigantic chasm, perpendicular to the first; which chasm, first taking a westerly curve and subsequently bending southwards and then eastwards, receives the river and conveys it in a capricious zigzag through a perfect maze of rocks. The great northern wall of the cataract over which the water flows is in places perfectly vertical, with few or none of those breaks or irregularities that one is accustomed to see under such circumstances. An enormous volcanic convulsion must have rent the rock asunder and produced the huge abyss into which one of the largest rivers in the world precipitates itself. Undoubtedly the powerful wearing of the waters has greatly modified the surface of the rocks, but it is not difficult for an observant eye to discover clearly that those deep scarps, now separated from each other, must at one time have been firmly united. The Zambesi, encountering upon its way the crevasse to which we have alluded, rushes into it in three grand cataracts, because a couple of islands which occupy two great spaces in the northern wall divide the stream into three separate branches. The first cataract is formed by a branch which passes to the south of the first island, an island which occupies, in the right angle assumed by the upper part of the cleft, the extreme west. This branch or arm consequently precipitates itself in the confined space open on the western side of the rectangle. It is 196 feet wide and has a perpendicular fall of 262 feet, tumbling into a basin whence the water overflows to the bottom of the abyss, there to unite itself to the rest in rapids and cascades that are almost invisible, owing to the thick cloud of vapour which envelopes the entire foot of the Falls. The island which separates that branch of the river is covered with the richest vegetation, the leafy shrubs extending to the very edge along which the water rushes, and presenting a most marvellous prospect. This is the smallest of the Falls, but it is the most beautiful, or, more correctly speaking, the only one that is really beautiful, for all else at Mozi-oa-tunia is sublimely horrible. That enormous gulf, black as is the basalt which forms it, dark and dense as is the cloud which enwraps it, would have been chosen, if known in biblical times, as an image of the infernal regions, a hell of water and darkness, more terrible perhaps than the hell of fire and light. Continuing our examination of the cataract, we find that the beginning of the northern wall, which starts from the western cascade, is occupied to an extent of some 218 yards by the island I have before alluded to, and which confines that branch of the river that constitutes the first Fall. It is the only point whence the entire wall is visible, simply because along that space of 218 yards the vapour does not completely conceal the depths. It was at that point I took my first measurements, and by means of two triangles I found the upper width of the rift to be 328 feet, and the perpendicular height of the wall 393 feet. This vertical height is even greater further to the eastward, because the trough goes on deepening to the channel through which the river escapes to the south. At that point likewise I obtained data for measuring the height. In my first measurements I had as my base the side of 328 feet, found to be the upper width of the rift; but it was necessary to see the foot of the wall, and I had to risk my life to do so. After the first island, where I made my measurements, comes the chief part of the cataract, being the portion comprised between the above island and Garden Island. In that spot the main body of the water rushes into the abyss in a compact mass, 1312 feet in length, and there, as is natural, we find the greatest depth. Then follows Garden Island, with a frontage of 132 feet to the rift, and afterwards the third Fall, composed of dozens of falls which occupy the entire space between Garden Island and the eastern extremity of the wall. This third Fall must be the most important in the rainy season, when the masses of rock which at other times divide the stream are concealed, and but one unbroken and enormous cataract meets the eye. As the water which runs from the two first falls and from part of the third near Garden Island rushes eastward, it meets the remainder of the third Fall coursing west, and the result

is a frightful seething whirlpool, whence the creamy waters rush, after the mad conflict, into the narrow rocky channel before alluded to, and go hissing away through the capricious zigzag chasm."

FIG. 4.—Mozi-Oa-Tunia (the Victoria Falls).—The West Falls.

In the appendices and throughout the work Major Pinto gives many astronomical and meteorological observations which are of real scientific value. Altogether his work is one of the most attractive and instructive of recent narratives of African travel.

ÉTIENNE HENRY SAINTE-CLAIRE DEVILLE.

WE regret to record a serious loss to French chemistry in the death of the celebrated professor, Sainte-Claire Deville, which occurred July 1, at Boulogne-sur-Seine. Étienne Henry Sainte-Claire Deville was born March 11, 1818, on the island of St. Thomas, in the Antilles, and was of Creole origin. Like most of the youth in the French colonies, he was sent to Paris to undertake a course of study. Of his two brothers who also proceeded to France to enter upon active careers, one, the late Charles Sainte-Claire Deville, devoted himself likewise to science, and we have had occasion more than once to refer to his remarkable geological investigations in these pages. While the Creole element has rarely lacked in the artistic and literary circles of the French capital, we believe that the two brothers in question furnish the only notable instance in which science has profited from the highly imaginative and versatile Creole temperament. It is related of the young Henry that on completing his collegiate studies, he hesitated for a long time in making his choice between music and science. His decision was due in a great measure to the enthusiasm awakened at the time by the brilliant lectures and no less brilliant investigations of Jean Baptiste Dumas. Guided by the counsels of the latter, he equipped a laboratory, and commenced a series of investigations so fertile of results that in a short time he was ranked among the most promising of the younger school of chemists. In 1844 he entered upon professorial duties in accepting the Chair of Chemistry in the Scientific Faculty of Besançon, where, notwithstanding his comparative youth, he was appointed dean of his faculty. In 1851 he was called upon to succeed Balard as Professor of Chemistry at the *École Normale* of Paris. Gladly exchanging the comparative obscurity of a provincial university town for the manifold advantages of a Parisian professorship, he devoted himself with such ardour to the duties of his new position that, after a short lapse of time, the laboratory of the *École Normale* became one of the central points of chemical investigation, not only in France but in all Europe. In 1854 he accepted, in addition to his usual duties, a lectureship at the Sorbonne, which, fourteen years later, was changed for a full professorship. His favourite field of activity remained, however, the *École Normale*, and it was with difficulty, some months since, that he felt himself called upon to relinquish active professorial duties in consequence of rapidly increasing feebleness.

As an investigator, Deville made his *début* in organic chemistry in 1840 with a remarkable study of turpentine oil and various derivatives of the terpenes. His carefully tabulated results form the chief basis of our present knowledge of the different isomeric states of this group. They were followed in 1842 by a research on toluene, the importance of which was only duly felt on the introduction of the aniline colours. After minor investigations of various resins, Deville abandoned organic chemistry

to devote himself almost exclusively to the inorganic branch, and announced in 1849 his first grand discovery, that of nitric oxide. By demonstrating the existence of this interesting and important compound, as resulting from the action of chlorine on silver nitrate, $2AgNO_3 + Cl_2 = 2AgCl + O + N_2O_5$, Deville did much to stimulate the theoretical speculation of the day, especially among the opponents of the school of Gerhardt, whose theories did not recognise the possibility of the existence of monobasic acid anhydrides. After a few years devoted to varied studies of metallic carbonates and new analytical processes, he commenced in 1855 the famous research on metallic aluminium, which proved to be one of the crowning features of his lifework. Furnished with ample means by the munificence of Napoleon III., he was enabled to carry out experiments on a large scale, and so rapid was his success that even in 1855 he displayed at the Exhibition of Paris massive bars of this handsome metal, which previously had scarcely been seen in a pure state. The study of this metal and its metallurgical production, as well as of the various compounds of aluminium, carried out during a series of years, forms one of the most remarkable and complete contributions made to inorganic chemistry within a recent period. Deville's perfected process for the preparation of aluminium, as carried out in the two French and the single English establishment in which alone this metal is obtained, consists essentially in heating the double salt of aluminium and sodium, $AlCl_3.NACl$, with metallic sodium, fluor-spar or cryolite being added as a flux. The metal thus obtained in the form of a solid regulus is used for a large variety of objects where lightness, strength, and freedom from oxidation are demanded, and forms the essential part of numerous valuable alloys. It has failed partly to meet the extended use to which Deville looked forward, on account of its comparatively high price and the difficulty of welding the metal. Among other industrial branches which we owe to Deville's efforts to create the manufacture of aluminium, such as the production of bauxit and cryolite, mention should especially be made of the manufacture of metallic sodium, the price of which sank in ten years from 2,000 francs to 15 francs per kilogramme. Deville's researches in this direction and his various methods of manufacture are to be found *in extenso* in his classical work, *De l'aluminium, ses propriétés, &c.*, 1859. In union with Caron he applied in 1863 the method found successful in the case of aluminium to the production of magnesium, and thereby created a second branch of industry. The manufacture of this metal, although confined to an annual production of about ten tons, is fully as interesting and ingenious as that which places aluminium within the reach of the industrial and scientific world. In this connection mention should be made of his exhaustive researches, chiefly in company with Débray, on the metals of the platinum group (1859—1862), in the course of which he succeeded for the first time in fusing large quantities of platinum by means of the oxyhydrogen blowpipe. The phenomena accompanying the high temperatures so all-important in the metallurgical operations just alluded to, gradually assumed a leading place amongst the subjects of Deville's researches. After successfully devising lamps and furnaces by means of which a high degree of heat was attainable, and methods by which the temperature could be measured, he proceeded to study a variety of reactions taking place at temperatures scarcely reached before his time. First among the results obtained in this direction reference should be made to the variety of crystallised minerals prepared artificially, such as willemite, greenockite, zircon, periclase, staurolite, &c. This branch of research has been so ably followed up by scholars of Deville, that but few natural minerals exist nowadays of which artificial counterparts have not been prepared. Of much greater importance were the numerous determinations of the vapour densities of bodies which are ordinarily solid, such as the chlorides of aluminium, of iron, and of various rare metals, by means of which the molecular weights of numerous compounds have been satisfactorily obtained. By far the most important of Deville's thermal investigations, those which have rendered the grandest services to theoretical chemistry, are connected with his noted discovery of the principle of dissociation in 1857. This principle, which explains a variety of hitherto anomalous occurrences among thermal phenomena, may briefly be considered as the property of many compound bodies to undergo partial decomposition under the influence of heat in confined spaces, until the liberated gas or vapour has attained a certain tension greater or less according to the temperature. So long as this temperature remains constant, no further decomposition takes place, neither does any portion of the separated elements recombine. If the temperature be raised decomposition recommences, and continues until a higher tension of the liberated gas or vapour, definite for that particular temperature, is attained. If the temperature falls, recomposition ensues, until the tension of the residual gas is reduced to that which corresponds with the lower temperature. The enunciation of this simple, but far-reaching principle has thrown light upon a number of phenomena, such as the formation of minerals, the apparent volatilisation of solids, &c., and has been the fruitful source of countless novel discoveries.

The number of different subjects touched upon by Deville during his long career of investigation, has been so great that we are forced to simply allude in conclusion to several notable researches, such as that on boron in company with Wöhler (1857), preparation of silicium, and its compounds with copper (1863), a new calorimeter, and the changes attendant upon the mixture of liquids (1870), the examination of a large variety of minerals and natural products, &c.

In reviewing the lifework of Sainte-Claire Deville, we are struck constantly by the predominance of one quality —that of simplicity; a quality so eminently characteristic of the man in his social relations, as well as in his scientific labours, that perhaps no phrase could describe him better than that of the French Bunsen. Like his great fellow-worker across the Rhine, he has been able to find abundant material for the exercise of his genius in attacking the still unsolved problems of inorganic chemistry; like him also he has held himself aloof in a great measure from the polemics prevalent in the modern school of chemists; the same charming simplicity characterises his apparatus, his methods, the few fundamental principles he has enunciated. As a professor Deville was deeply beloved by his students, to whom he was in turn greatly devoted; responding readily to all demands on his time and thought, and making use of his vast influence to further the interests of those who evinced special merit. His proverbial tenderness towards trembling candidates in the public examinations rendered him eminently popular in student circles.

"Voyons, Monsieur, de quoi est composée l'eau? . . . d'O?"

"Xygène," repondait l'élève.

"Et encore? . . . d'hy . . .?"

"Drogène," ajoutait le candidat.

"C'est cela, Monsieur, merci!"

Sainte-Claire Deville was elected a member of the French Academy in 1861. A year before he had been elected a honorary member of the Chemical Society of London. He was the recipient of numerous other marks of recognition from foreign societies and governments. A few years since he received the commission of preparing the normal international metre measure, a task which brought upon him much labour. While holding aloof from politics, Deville was highly regarded in the business

world, and was a director in the Parisian Gas Company and the Eastern Railway of France. His family relations were singularly happy. He leaves behind him a group of five sons. In addition to the treatise on aluminium already alluded to, Deville was the author, in company with Débray, of an exhaustive work in two volumes on the "Métallurgie du Platine" (1863).

T. H. N.

CONVERSAZIONE AT KING'S COLLEGE

ON Saturday, July 2, a brilliant and successful *conversazione*, given by the Council and the Academical Staff of King's College, brought to a conclusion the celebration of the fiftieth anniversary of the opening of the College. In the afternoon H.R.H. the Prince of Wales, accompanied by H.R.H. the Princess of Wales, distributed the College prizes to successful students, and the College rooms were converted into tastefully decorated drawing-rooms and picture galleries, in which were exhibited many very choice pictures and works of art.

The library was furnished with microscopes which had been lent by members of the Microscopic Society. The large entrance hall and the front of the College were brilliantly lighted by three Crompton electric lights, which burnt with remarkable steadiness throughout the evening. In the scientific department, the museum of King George III. contains an unrivalled collection of mechanical and physical apparatus, and is especially rich in apparatus of historic interest. The nucleus of the collection was presented to the College by Her Majesty the Queen in 1843, when the museum was opened by Prince Albert, who then witnessed some of the experiments of Sir Charles Wheatstone on the electric telegraph. Important additions have been made to the collection of apparatus by the Professors of Natural Philosophy, and at his death Sir Charles Wheatstone's valuable collection was bequeathed to the museum. Among the interesting features in the museum are: calculating machines of Cavendish and others, Appoldie centrifugal pump, Newcomen's model of his steam-engine, original forms of Daniell's battery, Siberian loadstone used for his induction spark by Faraday, original Wheatstone's bridge, early forms of stereoscope, early forms of electrical machines, polar clocks and shadow clocks, De Kempelen's talking machine.

From its foundation in 1868 the Physical Laboratory, now called the Wheatstone Laboratory, has been under the direction of Prof. W. Grylls Adams. Among the interesting apparatus exhibited in this department were the Wheatstone Collection of electrical apparatus for exhibition in Paris, dynamo-electric machines, diffraction spectra, an optical bench, showing interference of light, measuring polariscopes, with universal motions for the exact measurement of crystals, and vacuum tubes in great variety, including a very beautiful coronet. The great event of the evening in the Physical Department was the exhibition for the first time in England of the Faure's secondary battery or reservoir of electricity. Two boxes of this battery, which had been previously charged from a dynamo-electric machine, and had then been brought to the College, were capable of heating and keeping heated to bright redness a platinum wire 2 metres long and 1 millimetre in diameter. Six boxes were found to be sufficient to cause Swan electric lamps to glow brilliantly. Twelve of these boxes supplied a pedestal of Lane-Fox lamps, supplied by the British Electric Light Company, and during the evening the Physical Lecture Theatre was brilliantly illuminated by twenty Swan lamps of the latest type with the current from twelve other boxes of Faure's secondary battery. It was shown that by means of these boxes of electricity the lighting of private houses by electricity was already an accomplished fact.

THE COMET

WE have received the following communications:—

AT about 11h. 0m. G.M.T. on June 29 a transit of the "following" nuclear jet of the great comet over a star of 8m. was observed by Mr. N. E. Green, of 39, Circus Road, St. John's Wood, and by me, with a 12½-inch reflector belonging to Mr. Green. Definition was very good and tranquil. As the star became involved in the jet it gradually increased in size, and when seen through the brightest part of the jet traversed resembled an ill-defined planetary disk about 3″ in diameter. At this moment the comet seemed to have two nuclei similar in aspect and brightness.

The effect of the cometary matter on the star's image resembled that of ground glass, not that of fog; the image of the star, being dilated into a patch of nearly uniform brightness, instead of presenting a sharp central point with a surrounding halo. Cirro-stratus, passing into rain-cloud, produces on the appearance of the sun an effect the counterpart of that produced by the cometary emitted matter on the star. There was not sufficient light for the use of the spectroscope, the star, afterwards identified as B.D. + 65°, 519, being fainter than 8m.

The transit of the jet occupied about 3m., and the star slowly resumed its ordinary appearance and dimensions, the image *contracting* as the centre of the jet left the star behind. A transit of this kind has not frequently been observed, at least under such favourable conditions as to brightness and definition of the objects, and it is to be hoped that others may have been as fortunate as Mr. Green and the undersigned.

If the point which obeys the Newtonian law be a solid body, the observation just recorded seems to show that its true outline would probably be rendered unrecognisable, and its aspect totally altered by the (refractive?) power of the coma and jets.

CHARLES E. BURTON

38, Barclay Road, S.W., July 1

THE following is an extended list of places obtained with the transit-circle when the comet passed *sub Polo*:—

	Date.	Greenwich Mean Time of observation.	Observed R.A.	Observed North Polar distance (uncorrected for parallax)
		h m. s.	h m. s	° ′ ″
(*a*)[1]	June 23 ...	11 30 54·4 ...	5 34 55·2 ...	44 53 20·6
(*b*)	,, 24 ...	11 30 42·6 ...	5 38 39·9 ...	40 35 33·7
(*c*)	,, 25 ...	11 30 58·3 ...	5 42 52·2 ...	36 38 27·4
(*d*)	,, 27 ...	11 33 2·8	5 52 50·2 ...	20 46 5·8
(*e*)	,, 28 ...	— ...	— ...	26 49 45·0
(*f*)	,, 29 ...	11 37 39·3 ...	6 5 20·5 ...	24 11 37·9
(*g*)	,, 30 ...	11 41 3·9 ...	6 12 42·2 ...	21 50 26·3
(*h*)	July 1 ...	11 45 19·9 ..	6 20 55·5 ...	19 44 41·3
(*i*)	,, 2 ...	11 50 31·9 ..	6 30 4·9 ...	17 52 59·6

Remarks.—(*a*) The nucleus distinct but nebulous. Tail bright, and estimated 15° in length. Observation good.

(*b*) Observation difficult, owing to cloud.

(*c*) Nucleus better defined than on June 23, but not so bright. Length of tail estimated at 15°. Observation good.

(*d*) Observation fair, very cloudy. Tail 12°-15° long.

(*e*) Observed through short break in clouds. Tail 10° in length.

(*f*) Observation very good. Tail 10°.

(*g*) Observation very good. Nucleus smaller and fainter than on preceding nights. Tail 10°.

(*h*) Observation very good. Tail 9°.

(*i*) Very faint, observed through haze. Tail 8°.

Radcliffe Observatory, Oxford E. J. STONE

MY chief object in writing to-day is to explain a word in my letter of June 28 (p. 200) that is quite open to misinterpretation. In examining the head of Comet *b* 1881 with a small direct-vision spectroscope and a narrow slit, I saw, on June 27, three bright lines or bands on a faint continuous spectrum. Two of the lines were strong and

[1] The observed R.A. and G.M.T. for June 23, reported in last week's NATURE (p. 200), should be *decreased* one minute, as above.

near together, and of a bluish-green ; the third was much fainter and with very little apparent colour, but easily seen as a bright line. I called these "three green lines," as that was the general appearance in the field of view, and I had no intention of fixing the positions of the lines. The words however require explanation, as they would naturally be understood as restricting the bands to a definite part of the spectrum. On July 1, shortly before midnight, I examined the position of these lines more carefully, keeping the slit sufficiently open to secure a fairly strong continuous spectrum from the nucleus in the centre of the field, whilst the bright lines extended along the whole length of the slit. I could then see clearly that the two strong bands were in the green and blue, and that the fainter line was almost at the extremity of the more refrangible end of the spectrum visible in the small spectroscope used, and would therefore be situated in the violet or purple.

The comet on the night of July 1 was very much diminished in brilliancy, but at midnight it could still be traced by aid of a binocular through at least 7°. The nucleus shone as a 2·3 magnitude star, and under a considerable magnifying power it was found to have lost most of the interesting features of June 27. The double envelope, so well defined in outline a few days previous, had disappeared, and there now remained only the bright nucleus bounded towards the tail by two arcs, one on either side of the centre, from which those rays seemed to spring which moved slightly in the direction of the sun, and then bent round to help in forming the tail. A mass of light surrounded the head, but this faded away gradually into a nebulous outline. The light from the tail diminished very rapidly as the distance from the head increased. A *sub Polo* transit of the centre of the nucleus gave, for July 1, 11h. 50m. 7s. G.M.T., the following position uncorrected for parallax and aberration :—

R.A. 6h. 20m. 53s.·51 ; N. Decl. 70° 14′ 53″·7.

S. J. PERRY

Stonyhurst Observatory, Whalley, July 4

I INCLOSE three drawings of the comet made on the 27th, 29th, and 30th ult. On the 27th the bright jet extending from the nucleus was very plain, and gave the hydrocarbon spectrum very distinctly. No bands were seen in the tail, but only in the immediate proximity of the nucleus. On the 29th the comet was much fainter;

FIG. 1.

FIG. 2.—A = small star

the bright jet had disappeared, giving place to a fan, of which the left-hand side was the brighter. A small star was seen through the coma, *a*, which the comet rapidly passed.

FIG. 3

Last night (30th) the fan-shaped projection had narrowed considerably and apparently extended farther from the nucleus.

A. PERCY SMITH

Temple Observatory, Rugby, July 1

I HAVE made some sketches of this comet, and have taken some photographs with the 3-foot reflector. Particulars of the latter may be useful.

On the night of June 24 the comet, which was very brilliant, presented the appearance of Fig. 1; the nucleus very bright and some 6″ in diameter, and not in the centre of head. Photographs with two minutes' exposure gave a decided impression on the gelatine dry-plate; with twenty-one minutes' exposure the image was very dense,

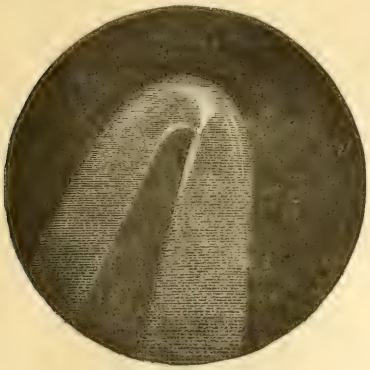

FIG. 1.—June 24, 12h. to 13h.

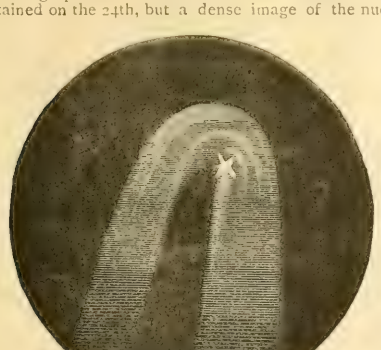
and the small bright tail that proceeded from the nucleus comes out well, but owing to the rapid motion in declination the image of the nucleus appears as a trail some quarter of an inch long.

On June 25 the appearance of the comet was altered, the club-footed mass of light had disappeared, and the nucleus presented a rayed appearance.

Photographs were taken with similar results to those obtained on the 24th, but a dense image of the nucleus



was got with one minute's exposure. The intensity of light must quite equal that of a seventh magnitude star. The small bright tail was still very apparent, but between it and the edge of the large tail proper there was a decided dark space on the *p* side. At 13h. 35m. the *f* side was noted to be much the brightest; this change must have taken place very suddenly, as it had been specially noted just before as being the faintest side of the tail. Fig. 2 was taken before this was noticed. Cloudy nights intervened till the 29th. I had in the meantime fitted a fine screw to the plate-holder, and found that by giving this screw a certain calculated part of a turn every half minute for twenty minutes, I got a fair negative (I beg to forward this for your inspection) without any of the distortion caused by the motion in declination.

FIG. 3.—June 29, 13h. 28m.

The comet was observed to have changed to a much more symmetrical form (see Fig. 3). The conditions under which the photographs were taken were not very favourable: the mirror and flat were not at the best as regards polish, and the plates were about two years old.

A. AINSLIE COMMIN

THE comet engaged the attention of the Paris Academy of Sciences at their sitting last Monday week, and we give the following extracts from the papers communicated.

Admiral Mouchez writes as follows:—"This comet, which was observed for the first time seventy-four years ago by an Italian monk on September 9, 1807, was observed by Pons eleven days afterwards at Marseilles on the 20th, and remained visible till March 27, 1808; during this long period it was possible to make a large number of observations, so that Bessel could for the first time calculate its elements; and he found that the period of its revolution must be comprised between 1404 and 2157 years, and was probably 1714 years. The calculations being revised and account taken of new perturbations, a period of 174 years was arrived at. The observations made during its second appearance will doubtless render it possible to determine the causes of perturbations or the errors of calculation and observation which have rendered its present return so unexpected.

"M. Tisserand has called my attention to a comet, not catalogued, but cited in Struyck's work, 'Vervolg van de Beschryving der Staatsterren' (Amsterdam, 1753), which appears to have been seen at the Cape of Good Hope in 1733, just seventy-four years previous to 1807; the want of precise observations, doubtless, did not allow of calculating the elements; but the identity of the period and the comet's appearance in the southern hemisphere lead us to suppose that it is the same comet as we observe now, and which, from some cause difficult to conceive, seems not to have been observed in Europe after its passage through perihelion. Perhaps the Dutch, to whom the Cape of Good Hope then belonged, will find in their archives some documents which will enable us to utilise this old observation, to which I have invited the attention of M. Oudemans, the learned and able astronomer of Utrecht."

M. Bigourdan says he first perceived the comet on June 22 at 13h. 30m. The following elements are deduced from the observation at Kiel (where the comet was seen two hours earlier than at Paris) on June 22, and the two following at Paris :—

1881.	Paris Mean Time.	Apparent Right Ascension.	Apparent Declination.
	h. m. s.	h. m. s.	° ′ ″
June 24 ...	9 51 26·0 ...	5 38 21·84 ...	+49 5 31·6
26 ...	10 46 5·8 ...	5 47 22·66 ...	+56 50 2·4

Perihelion passage, 1881, June 16·52806

log. q = 1·866099

Representation of mean observation

In longitude ... ... $(o - C)\cos\beta = -7''.7$
In latitude ... ... $o - C = -4''.3$

The last elements obtained by Bessel for the great comet of 1807 are as follows :—

Perihelion passage, 1807, September 18·74537 mean Paris time.

$\varpi = 270\ 54\ 42$
$\Omega = 266\ 47\ 11$ } Mean equin. 1807.
$i = 63\ 10\ 28$
log. q = 1·810,3158
e = 0·995,4878

With regard to the physical constitution of the comet, M. Wolf points out that while Coggia's comet (1874)—the only large comet visible on the horizon of Paris since spectrum analysis came into use—was at first telescopic, developed rapidly, and disappeared at the most interesting stage, the present comet comes to us already very much developed after its passage through perihelion. The transformations of the nucleus and its envelopes are extremely rapid (as the drawings show). In the large telescope the segmentation of the head, which Bond found in Donati's comet, was distinctly visible on June 24; the smallest instruments did not show it.

"The new comet represents, then, the second period of development of one of these curious stars, of which we have the first only in Coggia's comet. Its study enables us to follow the transformations of the envelopes, and to complete what information the comet of 1874 supplied.

"From the standpoint of spectrum analysis we may now correct a premature conclusion which might be deduced from our observations of Coggia's comet in 1874. That comet, from May 19, presented the continuous and nearly linear spectrum of the nucleus, traversed by the three bright bands characteristic of the light of comets (which I have found in more than a dozen of these stars). But on July 13, the evening of the last observation possible, the three bands had nearly disappeared, while the spectrum of the nucleus was become much brighter.

"Must we therefore conclude that the incandescent gas, carburetted hydrogen or other, to which these bands are due, disappear as the comet is developed, giving place to the light, proper or borrowed, of the nucleus? The observation of the new comet elucidates this. It rises rapidly from the horizon, in the same region of the sky where Coggia's comet descended to disappear, too quickly, below the horizon. Now on June 24 its spectrum, observed with the same instrument as was used in 1874, was reduced nearly to a continuous ribbon given by the nucleus; the nebulosity only gave a broad and very pale band, well terminated on the more refrangible side, diffuse on the other; the other bands of comets did not exist, or at least one could only suspect their existence in the neighbourhood of the nucleus. But yesterday (June 26) the comet was already far from the horizon, and when the sky was pure the three bright bands appeared with great distinctness. The green band especially was bright, longer than the two others, and distinctly limited on the less refrangible side (wave-length 516). On this side it seeemed bordered by a dark space, as in the spectrum of Coggia's camet. As in the latter the red is the only colour pretty visible in the spectrum of the nucleus, and it is slightly dilated. The ulterior observations will show whether these bands will continue to develop. We are put on our guard, in any case, against the effect resulting from difference of altitude of the comet.

"The total quantity of light given by the head of the comet is considerable, and many persons have tried to compare it to a star of the first magnitude. In reality its intrinsic brightness is very slight. I had occasion last night, by slightly displacing the telescope, to look at the spectrum of a star of fifth or sixth magnitude; the line of light produced was at least as bright as the spectrum of the nucleus."

Admiral Mouchez having put at M. Thollon's disposal the 14-in. equatorial of the Observatory, the latter made some spectroscopic observations of the comet on the nights of June 24, 25, and 26, with the following results :—

"The nucleus of the comet gives a pretty bright continuous spectrum, on which one can distinguish neither bands nor lines. The nebulosity surrounding the nucleus gives three bands which are detached on a continuous spectrum. One of them is very visible; the others are faint. Their position has been measured with great care. The measurements, repeated a large number of times, are more concordant than I could have hoped.

"The spectrum of bands furnished by the comet so resembles that given by the blue spirit flame that I consider them identical. This identity does not result merely from the aspect of the bands and their ratios of intensity, but also from their absolute position. The spectrum of the comet is, then, the spectrum of carbon or of one of its compounds. The sole difference I have met with is that the violet band given by alcohol is not seen in the spectrum of the comet; the absorption of the atmosphere suffices to account for this difference." M. Thollon is making further observations.

NOTES

THE "Chelini Memorial" volume takes the form of "Collectanea Mathematica," and is issued under the joint editorship of Professors Cremona and Beltrami (U. Hoepli, Milan). It contains thirty papers by twenty-eight sufficiently representative mathematicians, of whom sixteen are well-known Italian writers; of the remaining twelve, five (MM. Geiser, Kronecker, Reye, Schläfli, and Wolf) write in German, four (MM. Borchardt, Darboux, Hermite, and Mannheim) write in French. Of the three English contributors, Messrs. Cayley (on a differential equation), Hirst (on the complexes generated by two correlative planes) write in English, and Prof. H. J. S. Smith discourses in Latin "de fractionibus quibusdam continuis." There is a likeness of Chelini.

THE Government have appointed the Earl of Crawford and Balcarres Chief Commissioner, and Sir Charles T. Bright, Prof. D. E. Hughes, F.R.S., and Lieut.-Col. C. E. Webber, R.E., as Commissioners at the forthcoming Electrical Exhibition and Congress at Paris.

STUDENTS of Cretaceous geology will regret to hear that Griffiths, the well-known "fossil man" of Folkestone, has been disabled for many months by rheumatism, brought on by constant exposure during the past twenty-five years, in which he has daily extracted from the wet and slippery tract of Gault clay in East-weir Bay the remarkable series of mollusca with their pearly nacre preserved, plants, corals, crustacea, and reptilian remains that ornament not only the private collection of those who make

the Gault a subject of special study, but the national museums both of this country and of the New World. In addition to collecting by far the most perfect specimens of the Gault fauna and flora hitherto obtained, Griffiths has rendered an important service to science in carefully noting the bed or horizon from which each specimen was procured, which identification has formed the groundwork of the divisions which English geologists have been able to make in the Gault, and the correlation of these zones by M. Barrois and others with deposits occurring on the Continent. In consideration of these results, carried out by a working man under the difficulties of a struggle for life with circumstances, and the rigorous weather of the English Channel coast, it has been thought advisable to appeal to English geologists to raise a small fund which should render it unnecessary for work to be carried on when dangerous to health, and to tide him over present difficulties; towards this end a committee has been formed, consisting of Mr. W. Topley, F.G.S., Mr. F. G. H. Price, F.G.S., Prof. Boyd Dawkins, M.A., F.R.S., and Mr. C. E. De Rance, F.G.S., with Mr. F. G. H. Price of Messrs. Childs' Bank, Temple Bar, as treasurer, who will gladly receive subscriptions.

According to annual custom, the specimens added to the Museum of the College of Surgeons are now exhibited in the Council Room of the College, and will remain for inspection until the 13th inst., when they will be distributed in their proper places in the Museum. The number of additions, both to the Pathological and Physiological series, appears to be unusually large. Among the former we notice a novel feature in a collection illustrating vegetable pathology and teratology, prepared by Mr. S. S. Thattock; also a fine series showing the characteristic lesions produced by Indian dysentery, presented by Sir Joseph Fayrer. To the physiological, or rather zootomical, series the inhabitants of the Zoological Society's Gardens have yielded their usual quota of mortal remains, and almost every portion of the internal anatomy of the manatee, the external appearance of which was so familiar, during seventeen months, to the visitors of the Brighton Aquarium, can now be seen, neatly dissected and displayed in spirit. There are also some very beautiful preparations of human anatomy. Among the most striking objects shown in the osteological collection are a magnificent skull of a sea-elephant and a fine articulated skeleton of a sea-lion, both of which were obtained for the museum by the secretary to the Falkland Islands Company, Mr. F. Coleman. A series of skulls and skeletons of Veddahs, the aboriginal inhabitants of Ceylon, have been contributed by Mr. W. R. Kynsey. It is mentioned in Prof. Flower's report that the whole of the Barnard Davis collection, which numbers 1630 specimens, mostly crania, have been cleaned, arranged in the museum, and re catalogued during the year, and are now available for study. The report also refers to the appointment of an additional assistant curator, having special duties in the pathological department of the museum.

The Anniversary Meeting of the Sanitary Institute of Great Britain will be held at the Royal Institution, Albemarle Street, on Thursday, July 14, at 3 p.m. An address will be delivered by the Chairman of Council, Prof. S. F. B. F. De Chaumont, M.D., F.R.S., entitled, "Modern Sanitary Science;" and the medals and certificates awarded to the successful exhibitors at the Exhibition at Exeter in 1880 will be presented.

At a meeting of the joint committee of the Edinburgh Town Council, the Highland Society, and the Scotch Fisheries Improvement Association, held in Edinburgh on the 29th ult., a strong opinion was expressed in favour of the proposal to hold a Fisheries Exhibition in Edinburgh, of making it an international exhibition open to all countries, and of having it, if possible, in the Waverley Market, in April next year. An Executive Committee was appointed.

The University College, Nottingham, was opened on Thursday last, July 30, by His Royal Highness the Duke of Albany, in a brief ceremony. At a luncheon afterwards, given in the Albert Hall, the Duke made a thoughtful speech on the nature and aims of the Institution. We hope to return to the subject.

Belgium (according to *L'Électricité*) will take a considerable share in the forthcoming Paris Exhibition. The number of exhibitors is over a hundred. Among other exhibits the Jaspar regulator and the *lampe-soleil* of MM. Clerc and Bureau will compete prominently with the numerous other systems of electric lighting. Of telephone-specialists M. de Locht-Labye will show his pan-telephone in action, and M. Navez's researches will doubtless receive due attention. Meteorological instruments will be specially represented by those of M. Van Ryssel-berghe, with which the indications of a meteorograph at a distance are registered directly at Brussels Observatory. Col. Leboulangé will exhibit ballistic apparatus of special type, and his ingenious dromometer and dromoscope for controlling the velocity of trains, especially at dangerous points. Various kinds of telegraph wire will be shown, and a special interest will attach to the wires of phosphor bronze from the works of M. Montefiore Lévy; these wires have a conductivity four times that of iron, and their tenacity being also much greater, lines may be made in which the wire section is greatly reduced. An official and special catalogue is being prepared for the Belgian section it will comprise an introductory notice by M. Bonneux on electrical science and industry in that country.

A private visit was paid on Saturday last to the Channel tunnel experimental works by Sir E. Watkin, M.P. (chairman of the South-Eastern Railway Company), and a large party of scientific and other gentlemen. Very satisfactory progress was found to have been made at Abbot's Cliff since the last visit. The heading has now been advanced a total length of nearly half a mile. The tunnel is kept well free of water, and a good average rate of work is maintained. The work at the new shaft at Shakespeare's Cliff promises to be even more satisfactory. A very superior boring machine is used, and a more powerful engine is being fitted up to drive it.

The first general meeting of the Society of Chemical Industry was held on the 28th ult. in the hall of the Institute of Civil Engineers, Prof. Roscoe presiding. After the President's address papers were read on "Recent Legislation on Noxious Gases," by Mr. E. K. Muspratt; "The Brewing of Lager Beer," by Prof. C. Graham; and "Mechanical Furnaces," by Mr. James Mactear. This promising Society already numbers 300 members.

The Council of the University of Dublin have nominated Valentine Ball, M.A., of the Geological Survey of India, to the Professorship of Geology in the University of Dublin; this nomination however requires to be confirmed by a vote of the Board of Trinity College, Dublin. There were seven candidates.

M. W. de Fonvielle, editor of *L'Electricité*, and M. Lippmann, one of his contributors, made a balloon ascent on July 2, shortly after midnight. The descent took place near Rambouillet at a quarter past five, the distance traversed being 48 kilomètres. The balloonists carried with them a small Planté accumulator with a special safety electric lamp constructed by Trouvé, composed of a platinum wire inclosed in a glass tube. While the apparatus did not weigh more than 1 kilog. it gave sufficient light for reading the barometer and thermometer, and writing notes with accuracy. A special luminous compass for aëronauts will be constructed on this plan and sent to the Exhibition of Electricity.

The number of Chinese in the United States is now proved by the census to be very much less than has been commonly sup-

posed. It is only 105,717 (California possessing 75,122). It is true that the numbers have nearly doubled within the last ten years, but even at that rate they are not of a nature to cause any alarm such as appears to have been felt in some quarters. In the Eastern States the Chinese element is quite inappreciable among the foreign elements of population; New York contains but 942, Massachusetts 256, Illinois 214, &c.

THE scheme, earnestly advocated by the late Sir Thomas Moncreiffe, for providing Perth and Perthshire with a satisfactory natural history museum is now being realised, a handsome building in the Scottish baronial style having been built in South Tay Street with the funds provided. The ground floor contains a lecture-room, library, and laboratory or work-room, and the museum occupies the upper part of the building. To the rear a piece of ground has been secured on which additions more than doubling the accommodation could be built, but meantime the ground is to be used as a garden, in which all the more notable Perthshire plants will be grown. Access from the building can be easily obtained to two much larger lecture-halls than that in the museum, if necessary. The museum is to be strictly confined to the natural history, botany, and geology of Perthshire, excepting a small type collection, and should the project be rightly carried out (by the Perthshire Society of Natural Science) one of the most interesting and valuable local collections should thus be formed. The cost of the building (which is described in the current number of the *Scottish Naturalist*) has been upwards of 1,700*l.*, all of which has been subscribed. A further amount is required for furnishing, &c., and for this end a bazaar is to be held about the end of the year.

THE Literary and Antiquarian Society of Perth propose an extension of their Museum in Perth, the only one hitherto existing in the county, by building, at an estimated cost of 3000*l.*, a hall behind the present museum, mainly to accommodate the zoological collection (which comprises some 800 vertebrate and 2000 invertebrate forms). It is designed to present in this room a gradational view of animal life. A bazaar in aid of the proposed extension will be held on October 5 and 7. Subscriptions and donations may be sent to Mr. D. Hepburn, solicitor, 12, Charlotte Street, Perth, or to Dr. Bower, R.N., Montreal College, Perth.

AT the concluding meeting of the session of the Geologists' Association on Friday, July 1, a costly timepiece and ornaments were presented to Mr. J. Logan Lobley with the following address:—"The accompanying timepiece and ornaments are presented by the members of the Geologists' Association of London to their treasurer, J. Logan Lobley, Esq., F.G.S., F.R.G.S., in recognition of the valuable services he has rendered to the Association as Honorary Secretary, 1871–74, and Honorary Editor, 1871–81, and of the active interest he has always taken in its welfare and progress."

A BRANCH of the Baturite railway in Brazil has a gradient, which is probably the steepest in the world worked with a locomotive acting by simple adherence. This gradient is about 10 per cent., or 90 to 100 millimetres per metre. The line (described in last week's *La Nature*) is of narrow gauge, and extends from the port of Alfandega on the Atlantic to the town of Fortaleza, about 2 kilometres distance. The locomotive is from the Baldwin works in the United States; it has an adherent weight of 20,000 kilograms, and draws three loaded goods waggons or a single passenger car of the American type at a velocity of 20 kilom. per hour. By always limiting the weight to be drawn to an amount considerably under that of the engine, the regularity of the service on this line has been ensured during the two years it has been in use.

THE first part of a fourth edition of Griffith and Henfrey's useful Micrographic Dictionary has appeared. It is expected that the issue will be completed in twenty-one of these monthly parts, which will include important additions representing recent scientific progress. This work is known to aim especially at helping the microscopic observer to discover what any object is which may be presented to him, and by the aid of the Bibliography to refer to more extensive treatises for further details. A system is also adopted by which one is guided to a general knowledge of particular departments of science. There is an introduction on the use of the microscope. Dr. Griffith is assisted in the editing by the Rev. Mr. Berkeley and Prof. Rupert Jones.

WE have received an excellent specimen number of a new French engineering journal, entitled *L'Ingénieur*. The proprietors have acquired the right of reproduction, in France, of articles from our contemporary, *Engineering*, of which articles the new paper will largely consist.

M. FERDINAND DE LESSEPS has been elected president of the Société de Géographie of Paris.

THERE was recently landed at Marseilles a magnificent zebra which the King of Choa, Menelick II., has sent as a present to the President of the French Republic. This zebra, called the *Semaphore*, has been brought from Abyssinia by two Marseillais. The Société de Géographie, to which it was addressed from Aden, has intrusted it to the Marseilles Zoological Garden.

THE evening *fête* of the Royal Horticultural Society was held on the 28th ult. in the Gardens at South Kensington. Coloured lamps were disposed about the lawns, and here and there the cool plash of fountains was to be heard. The Siemens and Maxim electric lights were placed in the upper part of the Gardens, and in the lower part were two tents illuminated by the Brush electric light, and containing the plants of a flower-show, which continued next day. Brilliant effects were obtained with coloured fires behind the trees and the spray of the fountains.

THE Berwickshire Naturalists' Club commemorated the fiftieth year of its existence on the 29th ult. by a meeting at Grant's House, largely attended by members. Excursions were made to different places of interest in the locality, and before dinner Mr. James Hardy, joint secretary, was presented with a valuable microscope and 110*l.* in recognition of his long and arduous services. The Rev. Thomas Brown, Edinburgh, one of the oldest members of the club, presided.

FROM the *Colonies and India* we learn that the Meteorological Conference lately held at Sydney has agreed to a division of Australia into meteorological districts or aspects, to form the basis of weather telegrams and warnings. A cipher code has been arranged for weather telegrams to New Zealand, and the Queensland Government is to be asked to co-operate in the matter.

FROM an approximate summary of this year's census of Victoria, which has just been received from Mr. H. H. Hayter, the Government statist, it appears that the total population of the colony, including Chinese and Aborigines, is now 855,796, against 731,528 in 1871. The Chinese number 11,796, and the aborigines 768, the former showing a decrease of 6299 and the latter of 562.

THE additions to the Zoological Society's Gardens during the past week include a Purple-faced Monkey (*Semnopithecus leucoprymnus*) from India, presented by Lieut. W. V. Anson, R.N.; a Daubenton's Curassow (*Crax daubentoni*) from Venezuela, a Hawk's-billed Turtle (*Chelone imbricata*) from the East Indies, presented by Capt. King; a Rough Terrapin (*Clemmys punctularia*) from Trinidad, presented by Mr. Lachmere Guppy; ten Green Turtles (*Chelone viridis*) from Ascension presented by

Messrs. Weil Brothers; two Yellow Snakes (*Chilobothrus inornatus*) from Jamaica, presented by Mr. Chas. B. Masse; a Squirrel Monkey (*Chrysothrix sciurea*) from Demerara, a Military Macaw (*Ara militaris*) from South America, deposited; a Wapiti Deer (*Cervus canadensis*), two Hybrid Paradoxures (between *Paradoxurus leucomystax* and *P. stigmaticus*), born in the Gardens.

GEOGRAPHICAL NOTES

THE Geographical Society's *Proceedings* this month are chiefly occupied with the anniversary meeting at the end of May, and everything said and done on that occasion seems to have been carefully recorded. The only paper given is that by Mr. Minchin on Eastern Bolivia and the Gran Chaco, and it is illustrated by one of the best maps which the Society has published for some time. The geographical notes supply intelligence of matters which have not hitherto attracted notice in this country, though one at least is of considerable importance. We allude to the recent exploration of the Beni River by Dr. Heath of Wisconsin, which is a distinct addition to our knowledge of the Amazons' system. When fuller details, including Dr. Heath's observations for latitude and longitude, have come to hand, it will be for the first time possible to fix the precise position of the mouth of the magnificent river, best known as the Madre de Dios, which, until a few years ago, was believed by geographers to be a feeder of the Purus instead of the Madeira. Some information is also given as to the progress of exploration between the Rovuma and Lake Nyassa.

M. ABBÉ DESGODINS, who is well known for the excellent geographical work he has done in Eastern Tibet, contributes to *Les Missions Catholiques* the first part of some interesting notes on the marriage and other domestic customs of the Tibetans.

IT may be interesting to mention that in last week's number of the Society of Arts' *Journal* some useful notes are published on gums, resins, and waxes, which Mr. C. G. Warnford Lock has compiled from the journals of recent travellers. Especial prominence is given to india-rubber and the curious fossil resin known as gum copal.

M. ROUX has been intrusted by the Minister of Public Instruction and Fine Arts at Paris with a scientific mission to Tunis, and he has already begun the exploration of the region near the Constantine province of Algeria. He will afterwards undertake topographical and botanical investigations in the country between the Mejerba Valley and Cape Bon peninsula. Under the auspices of the same department M. Lantz is engaged in making natural history collections in some of the unknown parts of Madagascar.

M. BOULANGIER, a French Government engineer, has lately been engaged on a surveying expedition in Indo-China, in connection with the project for a railway. He went by a somewhat circuitous route from the frontier of French Cochin-China across Cambodia to Siam, made an especial study of the basin of the Tonlé-Sap, or Great Lake, which, according to his view, was formerly the head of the Gulf of Siam. The mountains south of Pursat must, therefore, have been an island, but the intervening low country becoming filled up they were joined to the mainland. As the result of his observations, M. Boulangier thinks that the Tonlé-sap will gradually silt up.

WE hear that Mr. Dorward, of the China Inland Mission, returned to Shanghai early in April from a five-months' journey in the province of Hunan. He is the only Protestant missionary who has ever traversed the route by which he returned from Hung-kiang to the neighbourhood of the Tung-ting Lake. Mr. Dorward also paid a flying visit to Kwei-yang-fu, the capital of the Kweichow province.

A PROMINENT paragraph in the *Standard* of last Saturday states that the "Geographical Society has received some interesting details of the fate of the Wybrants [*i.e.* Capt. Phipson-Wybrants] Expedition in Mozambique." We understand that there is absolutely no foundation for this statement, and the only effect of it is to inflict cruel disappointment on the relatives of the deceased members of this unfortunate expedition, regarding whose last days detailed particulars are anxiously awaited. Whether these will ever be known is, we fear, more than doubtful. The expedition was a purely private undertaking on the part of the late Capt. Phipson-Wybrants, and though he was aided with a loan of instruments, he was in no sense sent out by the Geographical Society.

THE Brazilian Section of the Lisbon Geographical Society, which was established a short time back, has commenced the publication at Rio de Janeiro of a periodical under the title of *Revista Mensal*. Dr. F. Mendes de Almeida is the editor-in-chief.

THE Bengal Asiatic Society have issued as part of their *Journal* Mr. Longworth Dawes' sketch of the Northern Balochi language, containing a grammar, vocabulary, and specimens of the language.

CIVILISATION AND BARBARISM IN SOUTH AFRICA

AT a meeting of the Anthropological Institute on the 28th ult. Sir Bartle Frere gave a lecture treating of the results of contact of civilised with uncivilised races in South Africa. The first part of the lecture dealt with the historical results of such contact in other countries, and the lecturer, after a sketch of the recent history and present condition of the various South African races, maintained that on the whole natives have increased in numbers as well as improved in physique and in intellectual status by contact with Europeans, and that there was also little real reason to doubt an improvement in moral status. The conditions required to raise and improve races like the Kaffirs were (1) a strong imperial government; (2) freedom from slavery and equality before the law. To secure these two requisites it was necessary (3) to determine whether the standard of moral and social progress shall be that of the European or that of the native races; (4) education according to English standards. The general results arrived at in the lecture were summarised in the following propositions:—(1) It is possible for the civilised to destroy by war the savage races, to expel, or repel, or turn them aside in their migrations; (2) proximity of civilised and savage races has led or is leading to the decay and probable extinction of the Bushman race. But this result is doubtful in the case of the Hottentot races, and is certainly not taking place with regard to the Bantu or Kaffir races; (3) the changes consequent on proximity of civilised and uncivilised races are an approximation to the European type of civilisation; (4) the essentials to such approximation are (*a*) a pax Romana or Anglicana, bringing with it (*b*) protection of life and property, which involves equality before the law, individual property in land, abolition of slavery, abolition of private rights of making war and of carrying arms without the authority of the supreme ruler; (*c*) power of local legislation on European principles, with a view to secure education in the arts of civilised life, taxation sufficient for state purposes, restrictions on the use of intoxicating substances, as measures essential to the full attainment of any one of the preceding objects.

INDIGO AND ITS ARTIFICIAL PRODUCTION

MORE than eleven years ago the speaker had the pleasure of bringing before this audience a discovery in synthetic chemistry of great interest and importance, viz. that of the artificial production of alizarine, the colouring substance of madder. To-day it is his privilege to point out the attainment of another equally striking case of synthesis, viz. the artificial formation of indigo. In this last instance, as in the former case, the world is indebted to German science, although to different individuals, for these interesting results, the synthesis of indigo having been achieved by Prof. Adolf Baeyer, the worthy successor of the illustrious Liebig in the University of Munich. Here then we have another proof of the fact that the study of the most intricate problems of organic chemistry, and those which appear to many to be furthest removed from any practical application, are in reality capable of yielding results having an absolute value measured by hundreds of thousands of pounds.

In proof of this assertion, it is only necessary to mention that the value of the indigo imported into this country in the year 1879 reached the enormous sum of close on two millions sterling, whilst the total production of the world is assessed at twice that amount; so that if, as is certainly not impossible, artificial indigo can be prepared at a price which will compete with the native product, a wide field is indeed open to its manufacturers.

[1] Lecture delivered at the Royal Institution, Friday, May 27, 1881, by Prof. H. E. Roscoe, LL.D., F.R.S.

Indigo, as is well known, is a colouring matter which has attracted attention from very early times. Cloth dyed with indigo has been found in the old Egyptian tombs. The method of preparing and using this colour is accurately described by both Pliny and Dioscorides, and the early inhabitants of these islands were well acquainted with indigo, which they obtained from the European indigo plant, *Isatis tinctoria*, the woad plant, or pastel. With this they dyed their garments and painted their skins. After the discovery of the passage to India by the Cape of Good Hope, the eastern indigo, derived from various species of *Indigofera*, gradually displaced woad as containing more of the colouring matter. But this was not accomplished without great opposition from the European growers of woad; and severe enactments were promulgated against the introduction of the foreign colouring matter, an edict condemning to death persons "who used that pernicious drug called devil's food," being issued by Henry the Fourth of France. The chief source of Indian indigo is the *Indigofera tinctoria*, an herbaceous plant raised from seed which is sown in either spring or autumn. The plant grows with a single stalk to a height of about three feet six inches, and about the thickness of a finger. It is usually cut for the first time in June or July, and a second or even a third cutting obtained later in the year. The value of the crop depends on the number of leaves which the plant puts forth, as it is in the leaves that the colouring principle is chiefly contained. Both the preparation of the colouring matter from the plant, and its employment as a dyeing agent, are carried on at the present day exactly as they have been for ages past. The description of the processes given by Dioscorides and Pliny tally exactly with the crude mode of manufacture carried on in Bengal at the present day.

Dioscorides says:—"Indigo used in dyeing is a purple-coloured froth formed at the top of the boiler; this is collected and dried by the manufacturer; that possessing a blue tint and being brittle is esteemed the most."

The identity of the blue colouring matter of woad and that of the Bengal plant was proved by Hellot, and by Planer and Trommsdorff at the end of the last century. These latter chemists showed that the blue colour of the woad can be sublimed, and thus obtained in the pure state, a fact which was first mentioned in the case of indigo by O'Brien in 1789, in his treatise on calico printing. Indigo thus purified is termed indigotin. It has been analysed by various chemists, who ascertained that its composition may be most simply expressed by the formula C_8H_5NO.

Concerning the origin of indigo in the leaves of the *Indigofera*, various and contradictory views have been held. Some have supposed that blue indigo exists ready formed in the plant; others, that white indigo is present, which on exposure to air is converted into indigo-blue. Schunck has, however, proved beyond doubt that the woad plant (*Isatis tinctoria*), the *Indigofera tinctoria* of India, and the Chinese and Japanese indigo plant (*Polygonum tinctorium*) contain neither indigo-blue nor white indigo ready formed. By careful treatment the leaves of all these indigo-yielding plants can be shown to contain a colourless principle termed indican, and that this easily decomposes, yielding a sugar-like body and indigo-blue. That white indigo is not present in the leaves is proved by the fact that this compound requires an alkali to be present in order to bring it into solution, whereas the sap of plants is always acid. The decomposition is represented by Schunck as follows:—

$$\underset{\text{Indican.}}{C_{26}H_{31}NO_{17}} + 2H_2O = \underset{\text{Indigotin.}}{C_8H_5NO} + \underset{\text{Indiglucin.}}{3C_6H_{10}O_5}.$$

So readily does this change from indican to indigo take place, that bruising the leaf or exposing it to great cold is sufficient to produce a blue stain. Even after mere immersion in cold alcohol or ether, when the chlorophyll has been removed the leaves appear blue, and this has been taken to show the pre-existence of indigo in the plant. But these appearances are deceptive, for Schunck has proved that if boiling alcohol or ether be used, the whole of the colour-producing body as well as the chlorophyll is removed, the leaves retaining only a faint yellow tinge, whilst the alcoholic extract contains no indigo blue, but on adding an acid to this liquid the indican is decomposed and indigo-blue is formed.

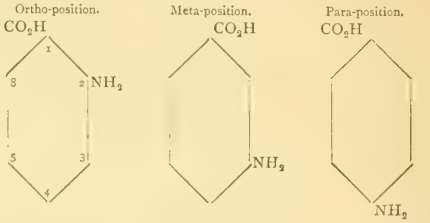
What now was the first step gained in our knowledge concerning the constitution of indigo, of which the simplest formula is C_8H_5NO?

Step No 1.—This was made so long ago as 1840, when Fritsche proved that aniline, $C_6H_5NH_2$, can be obtained from indigo. The name for this now well known substance is indeed derived from the Portuguese "anil," a word used to designate the blue colour from indigo. This result of Fritsche's is of great importance, as showing that indigo is built up from the well-known benzene ring C_6H_6, the skeleton of all the aromatic compounds, and moreover that it contains an amido group.

Step No. 2 was also made by Fritsche in the following year, when, by boiling indigo with soda and maganese dioxide, he obtained ortho-amido-benzoic acid, or, as he then termed it, anthranilic acid. The following is the reaction which here occurs:—

$$\underset{\text{Indigo.}}{C_8H_5NO} + O + 2H_2O = \underset{\text{Ortho-amido-benzoic acid.}}{C_7H_5NH_2O_2} + CH_2O_2.^1$$

What light does this fact shed upon the constitution of indigo? It shows (1) that one of the eight atoms of carbon in indigo can be readily separated from the rest; (2) that the carboxyl and the amido-group are in neighbouring positions in the benzene ring, viz. 1 and 2. For we have three isomeric acids of the above composition.



Step No. 3.—The next advance of importance in this somewhat complicated matter is the discovery by Erdmann and Laurent independently, that indigo on oxidation yields a crystalline body, which, however, possesses no colouring power, to which they gave the name of isatin.

$$\underset{\text{Indigo.}}{C_8H_5NO} + O = \underset{\text{Isatin.}}{C_8H_5NO_2}.$$

Step No. 4.—The reverse of this action, viz. the reduction of isatin to indigo, was accomplished by Baeyer and Emmerling in 1870 and 1878, by acting with phosphorus pentachloride on isatin, and by the reducing action of ammonium sulphide on the chloride thus formed.

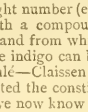
Understanding now something of the structure and of the relationships of the body which we wish to build up, let us see how this edifice has, in fact, been reared. Three processes have been successfully employed for carrying out this object. But of these three only one is of practical importance.

For the sake of completeness, let us, however, consider all three processes, although Nos. 1 and 2 are at present beyond the pale of practical schemes.

These three processes have certain points in common. (1) They all proceed from some compound containing the benzene nucleus. (2) They all start from compounds containing a nitrogen atom. (3) They all commence with an ortho-compound.

They differ from one another; inasmuch as process No. 1 starts from a compound containing seven atoms of carbon (instead of eight), and to this, therefore one more atom must be added; process No. 2, on the other hand, starts from a body which contains exactly the right number (eight) of carbon atoms; whilst No. 3 commences with a compound in which nine atoms of carbon are contained, and from which, therefore, one atom has to be abstracted before indigo can be reached.

Process No. 1 (Kekulé—Claissen and Shadwell).—So long ago as 1869 Kekulé predicted the constitution of isatin, and gave to it the formula which we now know that it possesses, viz.



Following up this view, Claissen and Shadwell, two of Kekulé's

[1] Bottinger, *Dent. Chem. Ges.* 1877, i. 269.

pupils, succeeded in preparing isatin, and, therefore, now indigo, from ortho-nitro-benzoic acid.

The following are the steps in the ascent :

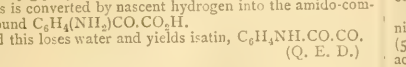
1. Ortho-nitro-benzoic acid acted on by phosphorus pentachloride yields the chloride $C_6H_4(NO_2)COCl$.
2. This latter heated with silver cyanide yields the nitril $C_6H_4(NO_2)CO.CN$.
3. On heating this with caustic potash it yields ortho-nitrophenylglyoxylic acid, $C_6H_4(NO_2)CO.CO_2H$.
4. This is converted by nascent hydrogen into the amido-compound $C_6H_4(NH_2)CO.CO_2H$.
5. And this loses water and yields isatin, $C_6H_4NH.CO.CO$. (Q. E. D.)

The reasons why this process will not work on a large scale are patent to all those who have had even bowing acquaintance with such unpleasant and costly bodies as phosphorus pentachloride or cyanogen.

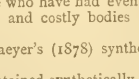
Process No. 2.—Baeyer's (1878) synthesis from ortho-nitrophenylacetic acid.

This acid can be obtained synthetically from toluol, and it is first converted into the amido-acid, which, like several ortho compounds, loses water, and is converted into a body called oxindol, from which isatin, and therefore indigo, can be obtained. The precise steps to be followed are :—

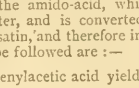
1. Ortho-amido-phenylacetic acid yields oxindol :



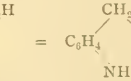
2. This on treatment with nitrous acid yields nitrosoxindol :



3. This again with nascent hydrogen gives amidoxindol :



4. Which on oxidation gives isatin,



(Q.E.D.)

This process, the feasibility of which had also been foreseen by Kekulé, is however not available as a practical scheme for various reasons.

Process No. 3.—This may be called the manufacturing process, and was also proposed by Baeyer. It starts from cinnamic acid, a substance contained in gum benzoin, balsam of Peru, and some few other aromatic bodies. These sources are, however, far too expensive to render this acid thus obtained available for manufacturing purposes. But Bertagnini, in 1856, had obtained cinnamic acid artificially from oil of bitter almonds, and other processes for the same purpose have since been carried out. Of these, that most likely to be widely adopted is the following practical modification by Dr. Caro of Mr. Perkin's beautiful synthesis of cinnamic acid :—

1. $C_6H_5CH_3 + 4Cl = C_6H_5CHCl_2 + 2HCl$.
   Toluene. Benzylene dichloride.
2. $C_6H_5CHCl_2 + 2CH_3.CO.O.Na =$
   Benzylene dichloride. Sodium acetate.
   $C_6H_5CH{=}CH.CO.OH + 2NaCl$.
   Cinnamic acid.

But why did Baeyer select this nine carbon acid from which to prepare indigo? For this he had several reasons. In the first place, it had long been known that all indigo compounds when heated with zinc dust yield indol, C_8H_7N, a body which stands therefore to indigo in the same relation as anthracene to alizarin, and Baeyer and Emmerling had so long ago as 1869 prepared this indol from ortho-nitro-cinnamic acid thus :

$$C_8H_6(NO_2)CO_2H = C_8H_7N + O_2 + CO_2.$$

Secondly, the ortho-nitro-cinnamic acid required (for we must remember that indigo is an ortho-compound and also contains nitrogen) can be readily prepared from cinnamic acid, and this itself again can be obtained on a large scale. Thirdly, this acid readily parts with one atom of carbon, and thus renders possible its conversion into eight-carbon indigo.

The next steps in the process are (3) the formation of ortho-nitro-cinnamic acid, (4) the conversion of this into its dibromide, (5) the separation from this of the two molecules of hydrobromic acid, giving rise to ortho-nitro-phenyl-propiolic acid, and (6), and lastly, the conversion of this latter into indigo by heating its alkaline solution with grape sugar, xanthate of soda, or other reducing agent. These reactions are thus represented :—

3. $C_6H_5CH{=}CHCOOH \qquad C_6H_4(NO_2)CH{=}CH.COOH$.
   Cinnamic acid yields Ortho-nitro-cinnamic acid.

In this process the para acid is also obtained, and as this is useless for the manufacture of indigo, it has to be removed. This is effected by converting the acids into their ethyl ethers, which, possessing different degrees of solubility, can be readily separated from one another :—

4. This is next converted into the dibromide
   $C_6H_4(NO_2)CHBr.CHBrCOOH$.

5. And by careful treatment with caustic soda this yields ortho-nitro-phenyl-propiolic acid, thus :—
   $C_6H_4(NO_2)CHBrCHBrCOOH + 2NaOH =$
   $C_6H_4(NO_2)C_2.COOH + 2NaBr + 2H_2O$.

6. $n[C_6H_4(NO_2)C_2.COOH + H_2 = C_8H_5NO + CO_2 + H_2O]$.
   Ortho-nitro-phenyl-propiolic acic. Indigotin.

(Q. E. D.)

The last of these reactions is in reality not so simple as the equation indicates. For only about 40 per cent. of indigo is obtained, whereas according to theory 68 per cent. should result. Indeed although, as we have seen, indigo can be prepared by these three methods, chemists are as yet in doubt as to its molecular weight, the probability being that the molecule of indigo contains twice 16 atoms of carbon, or has the formula $4(C_8H_5NO)$ or $C_{32}H_{20}N_4O_4$. Still it must be remembered that according to Sommaruga the vapour density of indigo is 9·45, a number corresponding to the simpler formula $C_{16}H_{10}N_2O_2$.

The artificial production of indigo may even now be said to be within measurable distance of commercial success, for the ortho-nitro-phenyl-propiolic acid, the colourless substance which on treatment with a reducing agent yields indigo-blue, is already in the hands of the Manchester calico printers, and is furnished by the Baden Company for alkali and aniline colours at the price of 6*s.* per lb. for a paste containing 25 per cent. of the dry acid.

With regard to the nature of the competition between the artificial and the natural colouring matters it is necessary to say a few words. In the first place, the present price at which the manufacturers are able to sell their propiolic acid is 50*s.* per kilo. But 100 parts of this can only yield, according to theory, 68·58 parts of indigo-blue, so that the price of the artificial (being 73*s.* per kilo.) is more than twice that of the pure natural colour. Hence competition with the natural dye-stuff is not to be thought of until the makers can reduce the price of dry propiolic acid to 20*s.* per kilo., and also obtain a theoretical yield from their acid. This may, or it may not, be some day accomplished, but at present it will not pay to produce indigo from nitro-phenyl-propiolic acid. Nevertheless a large field lies open in the immediate future for turning Baeyer's discovery to practical account. It is well known that a great loss of colouring matter occurs in all the processes now in use for either dyeing or printing with indigo. It has already been stated that a large percentage of indigo is lost in the "cold vats" in the sediment. Another portion is washed off and wasted after the numerous dippings, whilst in order to produce a pattern much indigo must be destroyed before it has entered into the fibre of the cloth. Moreover, the body of the piece is uselessly loaded with colour. In the processes of printing with indigo the losses are as great, or even greater, and, in addition, such considerable difficulties are met with, that only a few firms (Potter, Grafton in Manchester, and Schlieper in Elberfeld) have been successful in this

process. But a still more important fact remains, that no printing process exists in which indigo can be used in combination with other colours in the ordinary way, or without requiring some special mode of fixing after printing. Hence it is clear that the weak points of natural indigo lie in the absence of any good process for utilising the whole of its colouring matter, and in the impossibility, or at any rate great difficulty, of employing it in the ordinary madder styles of calico printing. Such were the reasons which induced the patentees to believe that although the artificial dye cannot be made at a price to compete with natural indigo for use in the ordinary dye-beck, it can even now be very largely used for styles to which the ordinary dye-stuff is inapplicable.

To begin with, Baeyer employed (Patent 1117) grape sugar as a reducing agent. The reduction in this case does not take place in the cold, and even on long standing only small traces of indigo are formed, but if heated to 70° or upwards the change takes place. Unfortunately this production of indigo-blue is rapidly followed by its reduction to indigo-white, and it is somewhat difficult in practice to stop the reaction at the right moment. But Dr. Caro of Mannheim found that sodium xanthate is free from many of the objections inherent to the glucose reduction process, inasmuch as the reaction then goes on in the cold. Moreover, he finds that the red isomeride of indigo-blue, Indirubin, which possesses a splendid red colour, but has little or no tinctorial power, is produced in less quantity in this case than when glucose is employed. On this cloth, alumina and iron mordants may be printed, and this afterwards dyed in alizarine, &c., or this colouring matter may also be printed on the cloth and the colour fixed by moderate steaming without damage to the indigo-blue. This process is now in actual use by printers both in England and on the Continent, so that, thanks especially to the talent and energy of Dr. Caro, Bayer's discovery has been practically applied within the short space of twelve months of its conception. Operations on a manufacturing scale have been successfully carried on in the Baden Soda and Aniline Works at Ludwigshafen for the last two months, and the directors see no reason why they should not be able to supply any demand, however great, which may be made for ortho-nitro-phenyl-propiolic acid.

The proper way of looking at this question at present is, therefore, to consider ortho-nitro-phenyl-propiolic acid and indigo as two distinct products not comparable with each other, inasmuch as the one can be put to uses for which the other is unfitted, and there is surely scope enough for both. Still, looking at the improvements which will every day be made in the manufacturing details, he must be a bold man who would assert the impossibility of competition with indigo in all its applications. For we must remember that we are only at the beginning of these researches in the indigo field. Baeyer and other workers will not stay their hands, and possibly other colouring matters of equal intensity and of equal stability to indigo may be obtained from other as yet unknown or unrecognised sources, and it is not improbable that these may turn out to be more formidable competitors in the race with natural indigo than ortho-nitro-phenyl-propiolic acid.

Looking at this question of the possible competition of artificial with the natural indigo from another point of view, it must, on the other hand, be borne in mind that the present mode of manufacturing indigo from the plant is extremely rude and imperfect, and that by an improved and more careful carrying out of the process, great saving in colouring matter may be effected, so that it may prove possible to produce a purer article at a lower price, and thus to counterbalance the production of the artificial material.

The potential importance, from a purely commercial point of view, of the manufacture, may be judged of by reference to the following statistics, showing that the annual value of the world's growth of indigo is no less than four millions sterling.

How far the artificial will drive out the natural colouring matter from the market cannot, as has been said, be foreseen. It is interesting, as the only instance of the kind on record, to cast a glance at the history of the production of the first of the artificial vegetable colouring matters, alizarin. In this case the increase in the quantity produced since its discovery in 1869 has been enormous, such indeed that the artificial colour has now entirely superseded the natural one, to the almost complete annihilation of the growth of madder-root. It appears that whilst for the ten years immediately preceding 1869 the average value of the annual imports of madder-root was over one million sterling,

Estimated Yearly Average of the Production of Indigo in the World, taken from the Total Crop for a Period of Ten Years.

	Pounds Weight.	Pounds Sterling.
Bengal, Tirhoot, Benares, and N. W. India	8,000,000	2,000,000
Madras and Kurpah	2,200,000	400,000
Manilla, Java, Bombay, &c.	...	500,000
Central America	2,250,000	600,000
China and elsewhere, consumed in the country ...	...	Say 500,000
		4,000,000

the imports of the same material during last year (1880) amounted only to 24,000*l.*, the whole difference being made up by the introduction of artificial alizarin. In 1868, no less a quantity than 60,000 tons of madder-root were sent into the market, this containing 600,000 kilos of pure natural alizarin. But in ten years later a quantity of artificial alizarin more than equal to the above amount was sent out from the various chemical factories. So that in ten years the artificial production had overtaken the natural growth, and the 3 or 400,000 acres of land which had hitherto been used for the growth of madder, can henceforward be better employed in growing corn or other articles of food. According to returns, for which the speaker had to thank Mr. Perkin, the estimated growth of madder in the world previous to 1869 was 90,000 tons, of the average value of 45*l.* per ton, representing a total of 4,050,000*l.*

Last year (1880) the estimated production of the artificial colouring matter was 14,000 tons, but this contains only 10 per cent. of pure alizarin. Reckoning 1 ton of the artificial colouring matter as equal to 9 tons of madder, the whole artificial product is equivalent to 126,000 tons of madder. The present value of these 14,000 tons of alizarin paste, at 122*l.* per ton, is 1,568,000*l.* That of 126,000 tons of madder at 45*l.* is 5,670,000*l.*, or a saving is effected by the use of alizarin of considerably over four millions sterling. In other words, we get our alizarin dyeing done now for less than one-third of the price which we had to pay to have it done with madder.

To Englishmen it is a somewhat mortifying reflection, that whilst the raw materials from which all these coal-tar colours are made are produced in our country, the finished and valuable colours are nearly all manufactured in Germany. The crude and inexpensive materials are, therefore, exported by us abroad, to be converted into colours having many hundred times the value, and these expensive colours have again to be bought by English dyers and calico-printers for use in our staple industries. The total annual value of manufactured coal-tar colours amounts to about three and a half millions; and as England, though furnishing all the raw material, makes herself only a small fraction of this quantity, but uses a large fraction, it is clear that she loses the profit on the manufacture. The causes of this fact, which we must acknowledge, viz., that Germany has driven England out of the field in this important branch of chemical manufacture, are probably various. In the first place, there is no doubt that much of the German success is due to the long-continued attention which their numerous universities have paid to the cultivation of Organic Chemistry as a pure science. For this is carried out with a degree of completeness, and to an extent, to which we in England are as yet strangers. Secondly, much again is to be attributed to the far more general recognition amongst German than amongst English men of business of the value, from a merely mercantile point of view, of high scientific training. In proof of this it may be mentioned that each of two of the largest German colour works employs no less a number than from twenty-five to thirty highly-educated scientific chemists, at salaries varying from 250*l.* to 5 or 600*l.* per annum. A third cause which doubtless exerts a great influence in this matter is the English law of patents. This, in the special case of colouring matters at least, offers no protection to English patentees against foreign infringement, for when these colours are once on the goods they cannot be identified. Foreign infringers can thus lower the price so that only the patentee, if skilful, can compete against them, and no English licencees of the patent

can exist. This may to some extent account for the reluctance which English capitalists feel in embarking in the manufacture of artificial colouring matters. That England possesses both in the scientific and in the practical direction ability equal to the occasion none can doubt. But be that as it may, the whole honour of the discovery of artificial indigo belongs to Germany and to the distinguished chemist Prof. Adolf Baeyer, whilst towards the solution of the difficult problem of its economic manufacture, the first successful steps have been taken by Dr. Caro and the Baden Aniline and Soda Works at Mannheim.

H. E. R.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

THE Linacre Chair of Physiology and Anatomy, lately held by Dr. Rolleston, and practically a chair of comparative zoology, will now be split into two, being succeeded by chairs of anatomy proper and physiology proper, with a more direct relation to the teaching of those subjects as part of a preliminary medical education, as was intended by Dr Linacre.

DR. OLIVER J. LODGE has been appointed to the Lyon Jones Professorship of Experimental Physics and Mathematics in University College, Liverpool, by the Councils of that College and of the Liverpool Royal Infirmary School of Medicine. Prof. Lodge has been some time Assistant-Professor of Physics at University College, London, and is the author of a work on elementary mechanics and various papers of original research.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 16.—"On the Stresses caused in the Interior of the Earth by the Weight of Continents and Mountains," by G. H. Darwin, F.R.S.

The existence of dry land proves that the earth's surface is not a figure of equilibrium appropriate for the diurnal rotation. Hence the interior of the earth must be in a state of stress, and as the land does not sink in, nor the sea-bed rise up, the materials of which the earth is made must be strong enough to bear this stress.

We are thus led to inquire how the stresses are distributed in the earth's mass, and what are magnitudes of the stresses.

In this paper a problem of the kind indicated is solved, by the use of certain results obtained by Sir William Thomson, for the case of a homogeneous incompressible elastic sphere, and the results are applied to the case of the earth.

If the earth be formed of a crust with a semi-fluid interior the stresses in that crust must be greater than if the whole mass be solid, far greater if the crust be thin.

The strength of an elastic solid is estimated by the difference between the greatest and least principal stresses, when it is on the point of breaking, or, according to the phraseology adopted, by the breaking stress-difference. The most familiar examples of breaking stress-difference are when a wire or rod is stretched or crushed until it breaks; then the breaking load divided by the area of the section of the wire or rod is the measure of the strength of the material. Stress-difference is thus to be measured by tons per square inch.

The problem is only solved for the class of inequalities called zonal harmonics; these consist of a number of waves running round the globes in parallels of latitude. The number of waves is determined by the order of the harmonic. In application to the earth the equator referred to may be any great circle, and is not necessarily the terrestrial equator. The second harmonic has only a single wave, and consists of an elevation at an equator and depression at the pole; this constitutes ellipticity of the spheroid. An harmonic of a high order may be described as a series of mountain chains, with intervening valleys, running round the globe in parallels of latitude, estimated with reference to the chosen equator.

In the case of the second harmonic it appears that the stress-difference rises to a maximum at the centre of the globe, and is constant all over the surface. The central stress-difference is eight times as great as the superficial.

Amongst other examples it is shown that if the homogeneous earth, with ellipticity $\frac{1}{230}$, were to stop rotating, the central stress-difference would be thirty-three tons per square inch, and it would rupture if made of any material excepting the finest steel.

The stresses produced by harmonic inequalities of high orders are next considered. This is in effect the case of a series of parallel mountains and valleys, corrugating a mean level surface with an infinite series of parallel ridges and furrows.

Numerical calculation shows that if we take a series of mountains, whose crests are 4000 meters, or about 13,000 feet above the intermediate valley-bottoms, formed of rock of specific gravity 2·8, then the maximum stress-difference is 2·6 tons per square inch (about the tenacity of cast tin); also if the mountain chains are 314 miles apart, the maximum stress-difference is reached at 50 miles below the mean surface. It appears that there is no stress at the surface, but the solution is only approximate, for it does not give the stress actually within the mountain masses, but gives correct results at some three or four miles below the mean surface.

The cases of the harmonics of the 4th and higher orders are also considered; and it is shown that, if we suppose them to exist on a sphere of the mean density and dimensions of the earth, and that the height of the elevation at the equator is in each case 1500 meters above the mean level of the sphere, then in each case the maximum stress-difference is about four tons per square inch. This maximum is reached in the case of the 4th harmonic at 1150 miles, and for the 12th at 350 miles, from the earth's surface.

It is then shown that the great terrestrial inequalities, such as Africa, the Atlantic Ocean, and America, are represented by an harmonic of the 4th order; and that, having regard to the mean density of the earth being about twice that of superficial rocks, the height of the elevation is to be taken as about 1500 meters.

Four tons per square inch is the crushing stress-difference of average granite. From these results it may be concluded that either the materials of the earth have about the strength of granite at 1000 miles from the surface, or they have a much greater strength nearer to the surface.

This investigation must be regarded as confirmatory of Sir William Thomson's view, that the earth is solid nearly throughout its whole mass. According to this view the lava which issues from volcanoes arises from the melting of solid rock, which exists at high temperature at points where the pressure is diminished, or else from comparatively small vesicles of rock in a molten condition.

Zoological Society, June 21.—Prof. W. H. Flower, F.R.S., president, in the chair.—The Secretary read a report on the additions that had been made to the Society's Menagerie during the month of May, 1881, amongst which special attention was called to an African Wild Ass (*Equus tæniopus*) from Upper Nubia, and a White-marked Duck (*Anas specularis*) from Antarctic America, both new to the collection.—Mr. R. Bowdler Sharpe exhibited a specimen of *Podilymbus podiceps*, stated to have been killed at Radipole, near Weymouth, in the winter of 1880–81.—Mr. W. A. Forbes read a paper on the Petrel called *Thallassidroma nereis*, by Gould. This, he showed, was not a true *Procellaria*, but must form the type of a new genus, to be called *Garrodia*, most closely allied to *Oceanites*, *Fregetta*, and *Pelagodroma*, and constituting with them a distinct family of "Tubinares," proposed to be called "Oceanitidæ."—Mr. W. A. Forbes read a paper on the conformation of the thoracic extremity of the trachea in the "Ratite" birds, noting specially a highly-developed syrinx in the genus *Rhea*, in which respect it differed from all the other genera comprised in that group.—A communication was read from Mr. George F. Bennett, C.M.Z.S., containing an account from personal observation of the habits of the *Echidna hystrix* of Australia.—Mr. G. A. Boulenger read a paper on the Lizards of the genera *Lacerta* and *Acanthodactylus*, prepared after a study of specimens in the British Museum.—Mr. F. C. Selous read a paper on the Antelopes that had come under his observation in Central South Africa. He exhibited a series of skins of the Bush-Buck (*Tragelaphus sylvaticus*), and pointed out their variations in different localities; also specimens of the Poku (*Cobus vardoni*), and the Speke's Antelope (*Tragelaphus Spekii*).—A communication was read from the Rev. O. P. Cambridge, describing some new genera and species of Araneidea.—Mr. Sclater pointed out the generic divisions of the Bucconidæ which he proposed to adopt in his monograph of the group now approaching completion, and characterised a new species of the family under the name *Nonnula cineracea*.—Mr. R. Bowdler Sharpe communicated some notes on new or rare species of Flycatchers lately added to the British Museum, principally from the Gould collection, and which it was proposed to call *Malurus cyanochlamys*, *Siphia obscura*, and *Rhipidura Macgillivrayi*.—A second paper by Mr. Sharpe contained an account of several collections of birds formed by Mr. W. B.

Pryer in the district of Sandakan, in North-Eastern Borneo. Two new species were described as *Lanius Schalowi* and *Dicæum Pryeri*.—Lieut.-Col. H. H. Godwin-Austen read the second portion of his paper on the land shells collected by Prof. J. Bayley Balfour during his recent expedition to the Island of Socotra. It referred to the family *Helicaceæ*.—Mr. G. E. Dobson communicated some notes on certain points in the muscular anatomy of the Green Monkey *Cercopithecus callithrix*.—Dr. A. Günther exhibited and read a description of a specimen of *Schedophilus medusophagus*, a Mediterranean fish new to the British fauna, lately captured off the coast of Ireland.

Anthropological Institute, June 14.—Major-General A. Pitt-Rivers, F.R.S., president, in the chair.—General Pitt-Rivers read a paper on the discovery of flint implements in the gravel of the Nile Valley, near Thebes. The worked flints were found embedded two or three metres deep in stratified gravel. Much interest has always been attached by anthropologists to this subject on account of its bearing on the antiquity of man. While in Europe we know that the use of stone for implements preceded the employment of metals, and was coeval with many animals that are now extinct, we have hitherto had no certain evidence that this period in northern regions, remote as it undoubtedly was, may not have been contemporaneous with the very earliest phase of Egyptian civilisation, traced backward as it is by the now accepted chronology of Manetho to an antiquity of 7000 years from the present time. Now, however, the evidence of human workmanship has been found in gravel deposits which had become so indurated that the ancient Egyptians were able to cut flat-topped tombs in it, supported by square pillars of gravel, which have retained their form uninjured to the present day, proving an enormously greater age for the flints embedded in the gravel, some of which were chiselled out of the sides of the tombs.—Mr. Alfred Tylor read a paper on the human fossil at Nice discovered by M. Ischa in December, 1880.—Mr. F. E. im Thurn read a paper on some stone implements from British Guiana.—Mr. J. Park Harrison exhibited a collection of Danish and French photographs.—The following papers were taken as read:—Mr. Gerard A. Kinahan, on sepulchral remains at Rathdown, co. Wicklow.—Mr. J. H. Madge, notes on some excavations made in Tumuli, near Copiapo, Chili, in June, 1880.—A number of specimens collected by Mr. Madge were exhibited, among which were two skulls, a quantity of pottery, and a cervical vertebra, in which was embedded a stone arrow-head.

PARIS

Academy of Sciences, June 27.—M. Wurtz in the chair.—The following papers were read:—Observations of Comet *b* 1881 (comet of 1807) at the Paris Observatory, by MM. Bigourdan, Wolf, and Thollon; note by M. Mouchez (see p. 223).—On the prolegomena of a new treatise on meteorology, published in Italy by M. Diamilla-Müller, by M. Faye. The first part is entitled "The Laws of Tempests (according to Faye's theory)," and M. Faye expresses satisfaction that his views seem to be gaining ground. In a letter to the author he suggests that in thunder-storms the source of electricity is not merely charged air (and icy particles) whirling downwards from upper regions, but electricity is developed in the act of gyration (reminding us of a Holtz machine working up a weak charge).—M. Janssen presented a photograph of the comet.—On Fuchsian functions, by M. Poincaré.—On the injuries to vegetation produced in treatment of phylloxerised vines, by M. Catta.—Influence of variations of atmospheric pressure on the duration of oscillations of the pendulum, by M. Saint-Loup. He found an advance of 0·077s. to occur in the day for a lowering of mercury pressure 10 mm. The experiment was of a preliminary nature.—Observations on the comet, and principally on the physical aspect of the nucleus and the tail, by M. Flammarion. He inclines to the view that comets' tails are not material—perhaps an excitation, electric or other, of ether. Their transparence favours this view. He also calculates that the tail of the comet of 1843, at the distance of the earth from the sun, must have swept space with a velocity of 64,000,000 of metres per second. Any molecule of matter flying at such a rate would not remain a single instant dependent on solar attraction, and would not go in a closed orbit.—On the surface with sixteen singular points, by M. Darboux.—On the surfaces for which the co-ordinates of any point are expressed by Abelian functions of two parameters, by M. Picard.—On a general means of determining the relations between the constants contained in a particular solution and those contained by the rational co-efficients of the corresponding differential equation, by M. Dillner.—On the vibratory forms of circular liquid surfaces, by M. Decharme. The internodal distances are inversely proportional to the corresponding numbers of vibrations; and this result is independent of the nature of the liquid. There is the greatest similarity between the vibratory forms in question and those of soapy pellicles of the same diameter.—On the employment of liquid prisms in the direct vision-spectroscope, by M. Zenger. On the anterior plane of a liquid prism he fixes a quartz prism of the same refringent angle, but placed in an opposite direction; the posterior face has, as usual, a plane parallel plate. The loss of light by reflection at the anterior and posterior surfaces is thus reduced to a minimum; the spectra are very intense, and the lines are well defined.—Photography of colours, by coloration of layers of coagulated albumen, by MM. Cros and Carpentier. M. Edm. Becquerel pointed out that it was not an immediate photographic reproduction of images with the natural colours of bodies, but a polychrome working by way of photographic impression, in which the tints of images are varied at will with the shades of the colouring matters used, and are not connected in any necessary manner with the colours of the active rays.—Pneumatic apparatus; pneole, spirelle, by M. de Romilly. In the pneole a jet of water sent upwards (say) by a turbine immediately enters an orifice (larger than that it comes from) of a vertical conical pipe, in which some of the water accumulates; and through this water numerous bubbles of air ascend, but cannot return. The water returns to the turbine by a lateral pipe. The spirelle (also for producing an air current) is entirely immersed in the circulating liquid (say in a turbine). It consists in one case simply of a slit of special position and nature in a tube which rises from the liquid, one edge of the slit is higher than the other.—On silicium, by MM. Schutzenberger and Colson.—On a cyanic ether of borneol, by M. Haller.—On the *rôle* of phosphoric acid in volcanic soils, by M. Ricciardi. This is a reply to M. de Gasparin.—On the volcanic soil of Catania, by M. Tedeschi di Ercole.—Unilateral phenomena, inhibitory and dynamogenic, due to an irritation of the cutaneous nerves by chloroform, by M. Brown-Séquard.—New mode of electric excitation of nerves and muscles, by M. d'Arsonval. In the apparatus described he aims at giving the induction current a mathematically definite value, easy to reproduce, rendering the electric excitation purely mechanical (not chemical), and at having an induced current of neutral direction (no positive or negative pole).—On the etiology and pathogeny of variola in the pigeon, and development of infectious microbes in lymph, by M. Jolyet.—Influence of nature of food on the development of the frog, by M. Yung. The substances tried stand in the following decreasingly favourable order:—Beef, fish, coagulated albumen of hens' eggs, albuminoid substance of frog's egg, vegetable substances (algæ). The two latter do not suffice to transform the tadpole into a frog. A purely albuminous substance suffices.—Metamorphosis of the Pedicellata, by M. Barrois.—On the formation of the cyst in muscular trichinosis, by M. Chatin.

SYMBOLIC LOGIC

Symbolic Logic. By John Venn, M.A., Fellow and Lecturer in the Moral Sciences, Gonville and Caius College, Cambridge. Pp. xxxix. 446. (London: Macmillan, 1881.)

MANY who are interested in the progress of logical science have looked forward to the appearance of this long-expected work as one likely to give them a logical treat. They will not be disappointed. It may be impossible to accept Mr. Venn's opinions as decisive of some points which he discusses, and it would not be difficult to indicate deficiencies; but we have no book which approaches the one before us in the thoroughness with which it opens up the logical questions of the day. With equal industry and ability Mr. Venn has gone over almost the whole literature of logic so far as it contains any germs of the scientific system associated with the name of Boole. Mr. Venn writes professedly as an admirer of Boole, and his work consists to a great extent of the matter of lectures upon Boole's logic, delivered under the inter-collegiate scheme of lecturing, which has now been in operation for about twelve years at Cambridge. Thus the book is substantially an exposition of Boole's Logic, and practically the only one which we have. Boole's own great work, "The Laws of Thought," appeared more than a quarter of a century ago (1854), and has never reached a second edition. It has been much more talked about than read.

If Mr. Venn then had done nothing more than publish a comparatively easy and readable exposition of Boole's profound but difficult treatise, he would have done a good work. But he has done a good deal more, because he has worked out the relation of Boole's system to all discoverable previous attempts at a symbolic or quasi-algebraic treatment of the syllogism, as also to all who have since Boole's time endeavoured to improve upon his system. The writings of almost one hundred logicians have been investigated by Mr. Venn, and not a few of these writers are practically unknown to English readers. If I mention the names, for instance, of Bolzano, Bardili, Dalgarno, Darjes, Lipschitz, Maass, Maimon, Segner, Semler, Servois, Weise, it is unlikely that the reader, unless he has made a very special study of logic, will ever have heard of most of these names before. A great change has taken place in the standard of scholarship expected of authors nowadays. During the last century philosophers calmly wrote down whatever came uppermost in their minds, in complete indifference to their ignorant predecessors. David Hume discovered and expounded the laws of the association of ideas, unconscious that it was all in Aristotle's works. Jeremy Bentham wrote upon logic with sublime confidence, although his reading had been confined to the compendiums of Sanderson and Isaac Watts. Now a man is expected to read everything about his subject before he writes anything. The late Sir William Hamilton of Edinburgh was the ideal of the new method, towards the introduction of which he much contributed. He had all the doctrines of logicians of various schools classified in his common-place books; but when he came to work out his own system of the syllogism, fell disease arrested him before the work was half done. It must require much judgment to use the bibliographic method, as one may call it, to an adequate, and yet not to an excessive extent.

Perhaps the most interesting chapter in the whole book is the last one, containing "Historic Notes," which are however merely supplementary to a great quantity of historical information given incidentally in the preceding chapters. The table on p. 407 is one of extreme interest. It shows and classifies in the clearest way no less than twenty-five apparently different modes in which logicians from the time of Leibnitz had attempted to represent symbolically the ordinary universal negative proposition, say, no S is P. Boole and Dr. Macfarlane, for instance, express it as denying the existence of the class of things S which is P. Hamilton introduced a clumsy wedge-shaped copula with a stroke across it to express negation; Darjes entirely misused well-known mathematical signs in the expression $+S-P$. Segner's formula is hardly better, namely $S<\!\!-P$. Mr. MacColl's notation, so recently the subject of discussion in the Mathematical Society, the *Educational Times*, and NATURE, is at least convenient, namely $S : P'$, though, as I venture to hold, only a disguised form of the equation $S = SP'$. But this single page gives matter for endless study, and Mr. Venn has conferred a great benefit upon logical students in opening up the subject of logical symbolism and logical method in its full extension, thus hastening the time when some decision can be arrived at.

There is, however, much that is novel in the volume. No author, for instance, has carried the diagrammatic representation of logical relations to anything like the same extent and perfection as Mr. Venn. Starting with the well-known circular diagrams, attributed to Euler, but traced back to earlier logicians, at any rate to Lange, Mr. Venn has succeeded in representing, by interlacing oval figures, the logical relations of four or even more terms. Although opinions may differ as to the value of the method, he has unquestionably worked out a complete and consistent system of diagrammatic reasoning, which carries the Eulerian idea to perfection. He has gone even further and has converted his diagrams into a kind of logical-diagram machine, which allows the elliptic segments representing classes to be selected and rejected mechanically. Of this remarkable device Mr. Venn (p. 122) says that "it would do very completely all that can be rationally expected of any logical machine. Certainly, as regards portability, nothing has been proposed to equal it, so far as I know." The latter statement may be certainly conceded, as the machine, though constructed needlessly large, is only five or six inches square, and three inches deep. So far, however, as I can judge from the somewhat brief and unexplicit description given by Mr. Venn, I cannot see how his machine can perform logical operations automatically. The selections of classes have to be guided and judged by the selector, and all that the mechanical arrangements effect is to select a whole class of elliptic segments at one movement of the fingers. This mechanical diagram, then, is analogous, as Mr. Venn remarks, to what has been described as "The Logical Abacus," but I do not think it can be called mechanical in the same degree as the logical machine.

In connection with these complex logical diagrams arises a curious and almost amusing illustration of the impossibility of knowing all that has been written on a subject. Mr. Venn in the Historic Notes has carefully gone over all logical writings known to him, and concludes (p. 426) that "hardly any attempts have been made to represent diagrammatically the combinations of four terms and upwards. The only serious attempt that I have seen in this way is by Bolzano." This statement is qualified in the Introduction or Preface (p. xxx.) by reference to H. Scheffler's "Naturgesetze," published in 1880. But if Mr. Venn had happened to look much nearer home, into the able "Outline of Logic for the Use of Teachers and Students," by the Rev. Francis Garden, M.A., Trinity College, Cambridge (1867), he would have found at p. 39 a diagram of five interlacing circles representing the relations of five terms. The diagram is thus described at the foot, "Genus A partly overlapped by genera B, C, D, and E, giving for species AB, ABC, AC, ACD, AD, ADE, AE, ACDE." The circles are broken in their unessential parts for the purpose of saving space. Mr. Venn's ellipses are in this respect much more convenient than circles, and the method of shading segments so as to show their propositional treatment to the eye is an important improvement; but the principle on which complex logical relations may be graphically represented is clearly seized by Mr. Garden.

Mr. Venn, although an ardent admirer of Boole, as indeed all advanced logicians must be, remarks (p. xxviii.) that his actual originality (priority?) was by no means so complete as is commonly supposed and asserted. But I am a little surprised to notice that Mr. Venn, although mentioning (p. 9) Thomas Solly's "Syllabus of Logic"[1] in relation to another matter, does not draw attention to the remarkable symbolical expression for the laws of the syllogism given therein. This brief work is throughout highly acute and philosophical.

The really important question which underlies the whole discussion of symbolic logic regards a technical and apparently minor point, namely the exclusive or unexclusive character of logical alternatives. When we say, for instance, that "capital is either fixed or circulating," is it implied *in the mere form of the statement* that capital cannot be at the same time fixed and circulating? Boole held so; or, at any rate, he held that any logical equation of his own system not conforming to this condition was imperfect and uninterpretable. But since Boole's time several logicians have contended that this condition was arbitrary, and in fact an error of Boole's. It is one chief purpose of Mr. Venn's book to uphold Boole's system in its integrity, and he writes in an attitude more or less of protest against subsequent innovators. This question has been noticed by Mr. MacColl in his letter (NATURE, vol. xxiv. pp. 124-126). It is however a question which requires chapters, if not books, for its adequate treatment; it is in fact to be judged by the success of a system, rather than by any simple direct arguments.

In regard to this letter of Mr. MacColl, I may point to the fact that I have already disputed the philosophical correctness of MacColl's symbolic innovations (NATURE, vol. xxiii. p. 485), while as regards the main principles of his calculus, it is out of the question that he should claim novelty. But we may nevertheless regret that Mr. Venn has referred in a slighting tone to investigations which have been carried out with great earnestness and acuteness. Mr. Venn does not speak in the same slighting manner of Prof. Schröder's essay, though I presume it is clear that the latter was as completely forestalled by previous writers unknown to him as was Mr. MacColl. In fact the way in which independent investigators are converging and meeting in a modified Boolian system is strong evidence that the questions so clearly set forth by Mr. Venn are becoming ripe for decision.

W. STANLEY JEVONS

[1] "A Syllabus of Logic, in which the views of Kant are generally adopted and the Laws of the Syllogism symbolically expressed," by Thomas Solly, Esq., late of Caius College, Cambridge. (Cambridge, 1839.)

ASTRONOMY FOR AMATEURS

A Cycle of Celestial Objects. Observed, Reduced, and Discussed by Admiral William Henry Smyth, R.N., K.S.F., D.C.L. Revised, Condensed, and greatly Enlarged by George F. Chambers, F.R.A.S., of the Inner Temple, Barrister-at-Law. (Oxford: The Clarendon Press, 1881.)

THERE can be, we think, little doubt that the publication of Admiral Smyth's "Cycle of Celestial Objects" powerfully stimulated a taste for astronomy amongst amateurs in this country. It was popular in style, and the contents generally were such as possessed interest for the numerous class of readers who neither require nor would appreciate more technical treatises. The gossiping notes interspersed throughout the work had their special attraction for many readers.

Mr. Chambers says he would not have undertaken the task of preparing a new edition of Smyth's work for the press had he not been convinced that there was a widespread desire for it. The copyright of the work, with the Admiral's notes, unpublished drawings, &c., had come into his hands, but there remained the digesting of these materials and interweaving them with the contents of the first edition. His programme he states to have been "so to revise, prune, and amplify Admiral Smyth's *Bedford Catalogue*, as to provide a Telescopist's Manual for Refractors up to, say, 8 inches of aperture, and to embody the progress of the science up to 1880, just as the original edition might have been considered fairly complete for 5 inches of aperture up to 1845." In carrying out this programme he has deemed it essential to include objects in the southern heavens, which we do not command in these latitudes.

It is to be understood that the new edition is confined to the *Cycle* proper, or to the second volume of the original work, the *Prolegomena* being, as Mr. Chambers remarks, for the most part written up to date in the last edition of his "Handbook of Astronomy." The number of objects included by Smyth was 850, the number in the present volume is 1604. Viewing the work as one intended for the guidance of the amateur as to the objects which it may be worth his while to observe, the additions, upon the selection of which considerable pains appear to have been bestowed, nevertheless include many stars that can hardly claim to be so regarded: we allude to such objects as Nos. 252, 334, 335, 346, 371, 396, 737, 974, 1025, 1149, &c. Perhaps a less extended list with fuller

descriptions of such as possess special interest would have been equally acceptable to amateurs generally.

We are not disposed to criticise too closely a volume involving a large expenditure of time and trouble for the benefit of those who occupy their leisure evenings in telescopic observations, but as the author expresses his desire to receive corrections or suggestions for future editions of his work, we will here refer to several defects which we have remarked in a pretty careful examination of it, in the hope that his attention may be directed to the kind of revision by which another edition may be improved. Some of the more remarkable objects appear to be treated with unfortunate brevity; we may instance the fine binary star 6 ϕ Eridani, of which a single epoch is given, without mention of the orbit having been determined by Dr. Doberck, or indeed any intimation that the star is in rapid motion: the first elements were assigned by Jacob. A still more noticeable case is that of α Centauri, one of the most interesting objects in the heavens, which is disposed of in half-a-dozen lines, without reference either to the elaborate investigations of its annual parallax since Henderson's time, to its large and well-established proper motion, or to the numerous orbits which have been computed, more especially those obtained since the passage of the peri-astron by Dr. Doberck and Dr. Elkin. Only two epochs are transcribed, one of them being the comparatively rough result of Gilliss at Santiago in 1851; in no instance would it have been better worth while to extract from the long series we possess, a sufficient number of measures to enable the reader to judge of the motion in the system. A very insufficient notice appears of Σ 518, a binary of which we may soon expect to have approximate elements, and the case of γ Coronæ Australis is quite misrepresented; from the few epochs given at p. 555, it might be inferred that there has been a direct change in the angle of position of about 30° in forty-five years, whereas there has been an actual *retrograde* motion in the angle of nearly 160°, upon which Schiaparelli calculated elements which represent the latest measures closely. Of the four cases where the author has appended orbits, in three (Castor, ζ Cancri, and ξ Ursæ Majoris) they are vitiated by typographical or other error.

Kirch's variable star in Cygnus, which Mr. Chambers calls χ^2, is the true χ Cygni of Bayer, to which letter Flamsteed's 17 Cygni has no claim; the cause of Flamsteed's misnomer was explained by Argelander many years since. The designation χ^2 is calculated to add to the doubt and confusion already existing as to this variable, of which the author unwittingly affords an illustration. The position assigned for 1890 is not that of the variable star (which is Lalande 37835), but is that of Piazzi XIX. 295, wrongly identified with Kirch's star by Piazzi, a circumstance to which, oddly enough, Mr. Chambers alludes in his notes, warning his readers against a mistake which he has himself just made. The correct place of the variable for 1890 is in R.A. 19h. 46m. 21s., Decl. 32° 38′·2.

The story of Cacciatore's supposed distant planet is left where it was by Smyth, the later calculations of Valz and Oeltzen, who showed that the motion indicated by Cacciatore could only apply to a minor planet, not being mentioned; and there are a number of other cases where the information supplied has not been brought up to date.

Mr. Chambers's volume has been handsomely printed at the Clarendon Press, and includes, for a frontispiece, the scale of colours, given by Smyth in his "Sidereal Chromatics," with the view to assist observers, in judging of the colours of the components of double stars.

OUR BOOK SHELF

Botany for Schools and Science Classes. By W. J. Browne, M.A., Lond., Inspector of National Schools. Second Edition, revised and enlarged. (Dublin: Sullivan Brothers, 1881.)

MR. BROWNE is the author of a variety of elementary mathematical books. In preparing this little manual of botany it may be presumed, therefore, that he has had to struggle with the difficulties which must always beset the amateur. The result resembles what one has often unfortunately met with in similar cases before. There is a want of simplicity in the treatment, much that is unessential and unnecessary for students of any grade, a good deal that is only of historical value, and what is worse, not a little that is downright error. This is the more unfortunate, as the questions at the end of the chapters and the examination papers which fill the last pages show that the book has a very definite aim. What, however, it may be asked, is likely to happen to examinees who reproduce such statements as the following? "*Coffee*.—The fruit consists of two halves, nearly hemispherical;" or "*Galls*—excrescences on oak, produced by an excretion thrown out round an egg deposited by an insect" (p. 98). On p. 60 the beech is given as affording an example of a capsule in its fruit; here the author has confounded the involucre with a pericarp. On the same page we find the following remark: "Around the seed . . . there is often developed a quantity of *albumen*, for the nourishment of the seed during germination"; on p. 55, "The germinal vesicle soon develops into the embryo or germ, containing the plantlet." This is on a par with the account of the process of fertilisation on p. 10, "A protoplasmic substance (*fovilla*) flows from the pollen-grain into the ovule and ripens it, so that it becomes a seed." The part of the book devoted to systematic and descriptive botany is better, though often open to criticism. If the writer had carefully studied *Penicillium* he would not have said, "The cells composing the branches (Fig. 89) are spores or *conidia*"; he has apparently been misled by his Fig. 89, which might do for one of the bog-oak ornaments sold in Dublin shops, but is a very inadequate representation of *Penicillium*. The examples of plant-descriptions are not sufficiently full, and are sometimes obscure, as for instance when the anthers of the common daisy are said to be "simple at base." The whole book still wants a thorough revision at the hands of a competent teacher to make it a safe guide for elementary students.

First Lessons in Practical Botany. By G. T. Bettany, M.A., B.Sc., F.L.S. (London: Macmillan and Co., 1881.)

THIS is an excellent little book. Its diligent study by teachers as well as pupils would give descriptive botany the real educational value which is so often claimed for it, and at bottom it no doubt possesses, if only the old type of manuals could be exterminated. What a weight would be removed from examiners' minds if examinees would really take to heart Mr. Bettany's impressive admonition (which should be hung in every examination room where plants are set for description):—"Do not *suppose* or *imagine* facts of structure which you cannot verify." It is really refreshing to come upon a manual, the object of which is to drill students in a healthy scientific method, and not merely to teach them how to impose on examiners with a show of sham and often preposterous knowledge, which has but a temporary hold on the memory and none on the understanding. The only genuine criti-

cism of a manual like this would proceed from one who had actually tested its use. Improvements will gradually suggest themselves; a few friendly suggestions might be even ventured upon offhand. On p. 63, for example, the following definition is open to objection:—"*Trichome*, a generic term for all organs developed by emergence from single cells of the epidermis." The chapter on Floral Diagrams is good. But it never seems to have been suggested that a genuine interest might be given to lessons in botany by making the pupils arrange the actual parts of the flower so as to form the diagram. All that is wanted is a flat square of cork covered with paper, on which four concentric circles are traced. It would be best to have three such squares for each pupil, with three, four, or five radiating lines drawn intersecting the circles, according as flowers with a ternary, quaternary, or quinary symmetry are to be examined. As each successive whorl of floral organs is removed, its parts should be pinned out in their proper relative positions by the pupil. The cyclical symmetry of the flower is clearly brought out in this way, even where it is apparently disguised. Some details in working the method would need a little elaboration, as, for example, the treatment of gamopetalous flowers; but this may be left to the ingenuity of teachers like Mr. Bettany.

Rabenhorst's Kryptogamen-Flora von Deutschland, Oesterreich und der Schweiz. Erster Band: 1 und 2 Lief. Pilze, von Dr. G. Winter. (Leipzig, 1881.)

FEW men have done their fellow-workers in science greater service, even if of a somewhat unobtrusive sort, than Dr. Ludwig Rabenhorst, whose recent death we announced with regret (NATURE, vol. xxiv. p. 108). His "Flora Algarum aquæ dulcis et submarinæ" is an indispensable guide to an immense labyrinth of species and genera which lie scattered up and down botanical literature. These are digested into a methodical enumeration which makes little attempt to be critical, but is content to bring the materials together just as every one who intends to study what has been done in any special group without such an aid must do for himself. Had Rabenhorst attempted more he would never have done the useful work that he did. One very convenient feature of his books is the brief synopsis of the genera of each group, accompanied by outline woodcuts of some leading types. Amongst organisms whose real affinities are often so obscure as the lower cryptogams, the utility of this plan cannot be sufficiently approved. The woodcuts often convey information at a glance which hours of study and comparison would not extract from the descriptions. The present work, of which two parts have so far appeared, is substantially a new edition of the author's "Deutschland's Kryptogamen-Flora," of which the first appeared as far back as 1844. The death of the original author may, it is to be hoped, have no effect on impeding its completion, as different groups are assigned to different hands, Dr. Winter commencing the fungi in the two parts before us. The scope of the whole work will be very much enlarged, but the same convenient features will be perpetuated. A speedy completion will be devoutly desired by all students of European Thallophytes.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*

[*The Editor urgently requests correspondents to keep their letters as short as possible. The pressure on his space is so great that it is impossible otherwise to ensure the appearance even of communications containing interesting and novel facts.*]

The Comet

FURTHER measures have been obtained at Greenwich of the position of the least refrangible edge for three of the four comet-bands with the following results:—

	Yellow band.	Green band.	Blue band.
Comet	5630·4±1·6 ...	5162·7±0·4 ...	4733·9±1·1
Bunsen Flame	5633·0 ...	5164·0 ...	4736·0
No. of Obs.	7 ...	26 ...	6

The identity of the comet-bands with those in the first spectrum of carbon appears to be clearly established, but in each case the comet-band is slightly shifted towards the blue. The displacement of the green band, if real, would indicate an approach of 47 ± 14 miles per second, whereas the comet was actually receding from the earth at the rate of about twenty miles per second. Such a displacement might, of course, be explained by an emission of cometary matter on the side towards the earth, but it would seem more probable that it is due to the circumstance that the edge of the comet-band is not quite sharp, and that a small portion on the red side is cut off. This would apply with still more force to the yellow and blue bands, which indicate somewhat larger displacements towards the blue. The displacements however, though all in the same direction, are not largely in excess of the probable errors. The comet-bands were compared with those given by vacuum-tubes containing cyanogen and marsh-gas, as well as with those of the Bunsen-burner flame, and three forms of spectroscope were used, viz. (1) the half-prism spectroscope with a dispersion of 18½° from A to H, and a magnifying power of 14; (2) the half-prism spectroscope reversed (as for prominence observations), giving a dispersion of 5° from A to H and great purity of spectrum, with a magnifying power of 28; and (3) the star spectroscope with a single prism of flint. No measures were obtained of the band in the violet, which was only seen on two occasions. It appeared to be sensibly coincident with the band in the first spectrum of carbon at 4311.

Mr. Maunder also noted several of the Fraunhofer lines in the continuous spectrum, in particular F (the position of which was determined by comparison with *Hβ*) and two other lines which were respectively near E and a strong double line at 5327.

W. H. M. CHRISTIE

Royal Observatory, Greenwich, July 12

I SUCCEEDED in photographing the comet in Auriga on Friday night, June 24. Since then I have taken several photographs of it. One made last night with an exposure of 2 hours 42 minutes shows the tail about 10° long. There are many stars on the plate, some shining through the tail.

HENRY DRAPER

The Physiology of Mind Reading

I HAVE received from Dr. G. M. Beard of New York (well known for his studies of Trance and related states) a letter in reference to the experiments with Mr. Bishop, of which Mr. Romanes has given an account in NATURE. Dr. Beard, writing before our experiments were carried out, mentions his own investigation, years ago, of much more remarkable performances than Mr. Bishop's, and incloses an article "On the Physiology of Mind-Reading," which he contributed to the *Popular Science Monthly* (New York) as far back as February, 1877. If this article had been shorter I would fain have asked you to reprint it, giving as it does a far more varied record of facts than came under our observation, and a series of carefully-drawn conclusions within which our conclusion falls. I will only say that if I had known of this article I should hardly have thought it worth while to spend time in the trial of Mr. Bishop's powers, or even had the curiosity to attend that first meeting amid the cloud of scientific witnesses.

G. CROOM ROBERTSON

July 9

Mind and Muscle-Reading

KINDLY allow me to correct a printer's error in my letter of last week. In describing the case of so-called thought-reading examined by myself in the clergyman's family in Derbyshire, I wrote: "The failures in *my* examination did not amount to one in ten, and were a smaller fraction when the children were not embarrassed by strangers," &c. The word "my" was printed "any," thus destroying the meaning of the sentence. I will just add that the clergyman in question is an old graduate of Trinity College, Dublin; his integrity is above suspicion, and even did not his position as a Christian minister negative the idea of trickery, the last experiment which I described disposes of this very natural explanation.

W. F. BARRETT

Special Solar Heat-Radiations and their Earth-felt Effects

THE well-filled lectures on Solar Physics by Prof. Balfour Stewart, published in NATURE, vol. xxiv. pp. 114, 150, will undoubtedly promote the study and assist the understanding of those subjects; and if a single one of the many items alluded to was not quite correctly described, that is neither surprising in itself nor likely to do much harm amidst the wealth of information which was at the same time both correctly stated and neatly conveyed. I should not therefore think myself now called on to notice one exceptional paragraph, but that it contains a most singular mistake in attributing to me conclusions from my own Edinburgh observations that are the very opposite of what I have often published between 1869 and the present time. Nor do I propose to make any positive complaint; for I rather admire the honesty of the lecturer who, after arguing for the more spotted periods of the sun's disk being its occasions of strongest heat evolutions, yet stated voluntarily and against himself that a directly opposite conclusion to his had been deduced by me from the unrivalled collection of more than thirty years of rock-thermometer observations on the Calton Hill. That is to say, that a certain eleven-year heat-wave shown by those thermometers coincided with, not the *maximum*, but the *minimum* spotted state of the sun; subject however to what the lecturer termed "a slight," but in reality a two or three year "lagging behind" the visible solar phenomenon.

Now let the sun, at any short-lived epoch, give forth an extra radiation of heat: I cannot imagine any person attempting or expecting to find its effects, after two or three *years*, as an acutely marked phenomenon in daily air and superficial earth-temperature observations. When therefore a very sharp phenomenon was marked on, or by, our thermometers, I looked for its explanation, not to what had occurred and passed away again several years before, but to something in nearly simultaneous progress on the sun. This something too, which I held forth upon even in my first paper on the subject in 1869 to the Royal Society, was ready at hand as a *vera causa;* and I ventured to describe it as "the ascending node" of the eleven-year sun-spot curve, or the time when a new cycle of sun-spots is not only well begun, but is in the act of its most rapid increase for any part of the cycle; just as a soda-water bottle effervesces most violently immediately after it is uncorked, rather than long afterwards, when some of its slowly-formed last bubbles are quietly escaping, and much more so than when it is not uncorked at all. In a letter too, printed in NATURE not two years ago, I showed how a great part of the solar action might be, and even had been immediate on our thermometers, in consequence of the very first action of a renovated sun, being a dispersion of the ordinary clouds *in situ*, whence an extra amount of direct sun-shine on the earth beneath them, producing a dry hot year to the agriculturists there.

The second effects I also showed might be an increased evaporation of distant ocean-surface; the formation thereby and bringing round of greater clouds, heavy rain, and precisely the cold seasons which our Edinburgh thermometers had shown, through thirty years, did generally follow the eleven-year wave of heat. Not, evidently, that the sun was then at a minimum of heat radiation, but that a screen of wet clouds had been drawn between it and that part of the earth where observations were going on.

Now something like this whole sequence of effects has just been experienced in Madeira, all in the course of this week, subsequent to the restored energy of sun-spot manifestation and the earth-answering electric cloud of last Sunday, as I wrote to you next day.

Now that, or the first day after the specified occurrence, proved scorchingly hot, with a blue sky and the maximum shade temperature of the season, thus far.

The second day after, a thick screen of clouds was drawn between us and the sun, while the trade-wind was not only restored on the adjacent sea, but with an excess of violence more like that which is felt about Teneriffe: viz, a more southern, and therefore more sun-governed, island.

But the third day after, not only was the sun again totally invisible on account of cloud, but to the surprise of all Madeira there was a heavy, vertical downpour of rain all day long. Old residents protested that they had never, for ten years at least, known anything of the kind at midsummer season. "Precisely so," I replied; "but in the Cape de Verde Islands still further south, and more under solar dominion than even Teneriffe, you will find that every year, the sun coming to the highest northern declination is marked by heavy tropical rains. Wherefore, if Madeira is now visited in the end of June by Cape de Verde solsticial rains, be assured that the sun is at this moment shining above the clouds over Madeira with much more than his usual annual force."

But though as I write, I would seek to draw the attention of your clever lecturer to unusual solar action being often attended with earth-phenomena which lag behind a few hours only, rather than several years, I do hope he will also obtain a perusal of my paper of 1869 from the Royal Society, Burlington House, London, and take note of the forty or more year cycle, as well as other shorter ones there alluded to; for the standard eleven-year cycle, of which we have now begun a new example, will never be completely definable without knowing on each occasion how far the others are mixed up with it. Thus we had, for instance, in August last year, that eleven-year cycle's *maximum* of temperature which I had pre-announced in print ten years before; but it was very near being lost to observation by occurring not far from the middle of the long-enduring *minimum* of the forty-five years' cycle, whose prime origin is as certainly solar as that of the eleven-year, and even then much shorter cycles of twelve or fifteen days only, of which I have noted several examples since I have been here.

Phenomena of Clouds

THE letter from Prof. Smyth (vol. xxiv. p. 212) recalls to my mind a phenomenon I witnessed several years ago in Arran. I was staying at Strathwhillan, on the north side of Brodick Bay, and looking northward had a full view of Goatfell and Mauldoon. The latter resembles an immense mound heaped up against the eastern side of the former. Snow had recently fallen and coated both. Then a south-easterly wind, coming up and across the firth, caused a cloud to be formed at a considerable elevation above the hills, having its under surface outlined in correct correspondence with the outlining of the subjacent mountains. This contour the cloud retained in seeming fixity for several hours. I attributed its continued existence to the effects of unequal radiation between the cold snow-covered hills and the warmer moisture-laden current above. Whether my surmise was correct, and whether the "central fixity" over Madeira can be referred to the same cause, I leave to the consideration of those more scientifically informed than I. Cambuslang, July 8

Early English Pendulum Measures

I FIND in a volume entitled "Metrology, or Weights and Measures of Great Britain and France," by P. Kelly, "Master of the Finsbury Square Academy, London," in 1816, a list of some of the old pendulum experiments of the last century, which contains some indications quite new to me. I am in hopes that if you will allow me space enough to make them known I may perhaps hear where further information is to be found. One of the measurements which he of course mentions is that of Graham. It is rather strange that though every one of the old writers mentions Graham's experiments confidently, I have hitherto failed to find any account whatever of those experiments. The other observers mentioned by Kelly—and so far as I know by him only—are "Emerson," "Desaguilliers" [who always wrote under the name of Desaguliers], "Rotherham," and "Sir Jonas Moore." The mention is not a mere hearsay repetition of their names in this connection, as he gives the *lengths* found by each for London.

In direct connection I may remark that every one knows that the pendulum has been over and over again mentioned and treated as an ultimate appeal in case of failure of other satisfactory means of restoring national standards. In fact its *earliest* use was for this purpose *only*—except of course in horology. Is it not then a strange thing that it was *never*—during the whole of the century and a half which so regarded it—used as a medium of comparison of actual national standards? In Graham's time the relation of the French and English units of measure was so uncertain that the pendulum, with all its failings, was quite competent to establish a firmer one. Newton's table

of the variation of the seconds' pendulum with latitude was quite trustworthy enough (not to say correct enough) to furnish the geographical difference between London and Paris lengths. Yet as a fact the pendulum never was so appealed to. Yet to this day it is still not uncommonly taught that the pendulum is the proper *natural* standard of reference. In 1816 of course such was the nearly universal dogma.

I say "never," but perhaps one or other of the above observers may be adduced to confute me. J. HERSCHEL

Collingwood, July 11

Faure's Secondary Battery

IN your issue of last week you gave an account of the *soirée* held at King's College, London, on the evening of July 2, and in this account it is stated that "the great event of the evening was the exhibition for the *first* time in England of M. Faure's secondary battery."

At the *soirées* given by the Mayor of Nottingham on the evenings of June 30 and July 3 in connection with the opening of the College by H.R.H. Prince Leopold, I had the pleasure of exhibiting to large audiences one of M. Faure's new batteries. Sheets of lead were bent up into the form of shallow trays, one foot square and one inch deep; in each of these was placed a layer of red lead, then a layer of flannel, then a layer of red lead, and lastly another lead plate. These trays to the number of six were then piled one above the other, after being filled with dilute acid. The cells being connected in series, were polarised by a 10-cell battery of Grove's cells, and after twenty minutes' charging, had taken up a very large quantity of electricity. At a short lecture given during the evening the charged Faure battery was connected with a Gramme machine, and drove it round with considerable velocity for some minutes. After thus employing part of the charge the remainder was used for heating several inches of platinum wire, and for driving for a few seconds a simple form of magneto-electric engine. These experiments amply convinced those present of the practical character of M. Faure's invention. As I have not had the opportunity of examining one of the original batteries of the inventor, I was obliged to make up this experimental form. It is however a convenient form for lecture-room demonstration, as it permits the structure of the battery to be exhibited to an audience. The enormous superiority of M. Faure's cell over the old form of Planté cell is evident at once on experimenting with it. J. A. FLEMING

Earthquake in Van

SINCE my former letter I have had an opportunity of visiting the region most affected by the earthquake of May 30, and have obtained some further particulars about it. Its greatest severity seems to have been felt at the Armenian village of Teghourt, lying at the foot of the Nimroud Dagh, at a distance, judging by eye, of not more than four miles from the edge of the crater. This village has been almost entirely destroyed, with the loss of ninety-three lives. By the same shock about 200 houses were thrown down or more or less damaged in the aggregation of hamlets named Akhlat, some six or seven miles further distant from the Nimroud Dagh. Here however happily only two lives were lost and a few persons were injured. On June 9, in the evening, a second shock took place of less violence, which partially damaged a third village, Sipratzor, lying between the other two. As far as I was able to learn these villages were the only localities in which buildings were actually thrown down, though cracks were caused in walls, &c., in other places. The three villages are all in the direct line between the two great extinct volcanoes of the Nimroud Dagh and Sipan Dagh, which fact leads to the conjecture that there may be a line of least resistance joining the two mountains. All three villages, however, are nearer to Nimroud than to Sipan. The greater severity of the shock at Teghourt, the nearest village to Nimroud, may have been due to the latter having been the centre of the disturbance, but it may also have been caused by the fact that the village is built directly upon the solid rock of an ancient lava-bed. The only observation I was able to obtain of the direction of the earthquake wave was communicated to me at a village lying due east of the Nimroud Dagh. Here it was said that the wave came from the south, which would look as if the centre of disturbance were in the Central Kurdistan mountains, not in Nimroud; but one doubtful observation is of course not enough to establish such a point.

Whilst in the neighbourhood I took the opportunity of visiting the Nimroud Dagh. The mountain rises in a very gentle slope, so that it is possible to ride the whole way up and into the crater. The edge of the crater, where we crossed it, is 2810 feet above the Lake of Van by aneroid and about six miles distant from it; some parts of the walls however rise 500 feet or so higher, the most elevated points being to the north and south. The crater is a vast, nearly perfectly circular, hollow, between four and five miles across, the floor of which is an irregular flat dome, partly covered with herbage and partly with dwarf birch and beech and a creeping yew. Among the undulations of the dome, and especially in the depressed ring between the dome and the walls of the crater, are situated some six or seven tarns. One of these, on the margin of which we stopped to rest, is fed by hot springs, which bubble up at numerous points near its edge. I had no thermometer to ascertain the temperature of the water, but I found that one spring, which rose in a small basin almost cut off from the rest of the lake, was just about as hot as I could bear to keep my hand in. This tarn is 880 feet lower than the edge of the crater where we crossed it, this being the lowest point in the whole circuit. I saw no sign of vaporous exhalation, although local tradition has it that the mountain was active not more than four centuries ago; but time did not permit me to explore the whole of the great interior space. EMILIUS CLAYTON

Van, Turkey-in-Asia, June 20

Meteors

SEVERAL splendid meteors having lately been visible, the following observations may be worthy of note in NATURE. I may add that the most brilliant meteor was the one recorded in your columns (vol. xxiv. p. 189).

June 24, 10h. 28m., a very large bright orange coloured meteor equal to Jupiter appeared near Vega.

At 11h. 29m. a deep orange-coloured meteor, larger and brighter, than Jupiter, crossed the extremity of the comet's tail. It left a short bright streak.

June 25, 10h. 52m., a yellowish-white meteor, as bright as Vega, appeared near ζ Cygni.

At 12h. 4m. a white meteor, as bright as Jupiter, appeared just south of x Draconis, and after pursuing a wavy path, disappeared near γ Ursæ Majoris. It left a short streak.

July 3, 10h. 23m. a yellow meteor, nearly as bright as Jupiter, appeared just east of Polaris, travelled slowly in a wavy path, and disappeared north of β Cassiopei.

It will be observed that three out of these five meteors appeared in that part of the sky occupied by the comet, and also that two of them pursued wavy or zig-zag paths. B. J. HOPKINS

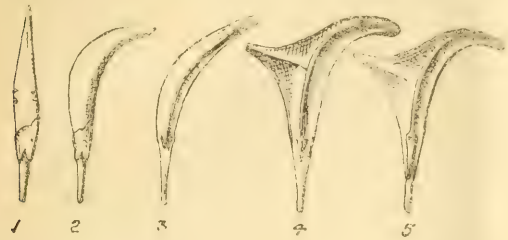
79, Marlborough Road, Dalston, E., July 5

The W-Pattern of Paddles

IN your impression of the 2nd ult. allusion is made to the origin of the W pattern which occurs upon paddles from the Solomon Isles. Without illustration it is difficult to understand the transitions which have taken place, but with the objects before you their history is easily read. I therefore inclose sketches; they are all from the same locality. In Fig. 1 it is seen that the swell of the blade of the paddle has suggested the idea of a fish's body, and accordingly the head with the mouth and eyes of a fish have been carved in their proper place. In Fig. 2 the same occurs, except that the blade is bent, probably to adapt the paddle to steering purposes, or for some other object. These two specimens represent the head of a fish in its realistic form. The progress of ornamentation is from realism to conventionalism. By comparing Fig. 3 with the foregoing it is easily seen that the W represents the mouth and sides of a fish's head reduced to straight lines, the eyes having disappeared. In all the specimens in my possession its position is always that in which the true fish's head occurs in the realistic specimens. In Fig. 4 a further change has taken place, the mouth is omitted, and the sides of the head have been brought together in a point, thus forming a simple triangle. Possibly the idea of a fish's head may have been altogether lost in this stage of the ornament, but in the next example, Fig. 5, the idea revives again, as so frequently happens in like cases, without recurring to the original model. Two eyes are seen to be inserted in the place where one occurred in the realistic specimens, the mouth still being deficient.

There can be little doubt, I think, that this interpretation

affords a true sequence of ideas that have taken place in the minds of the savages who made these things. And it is in complete analogy with the development of ornamentation in other places, of which several examples are in my museum. The interest which attaches to such specimens of savage art and ornament is purely psychological. Taken as the representatives of ideas, and arranged to show the development of ideas, they serve important purposes in the study of social evolution, ex-



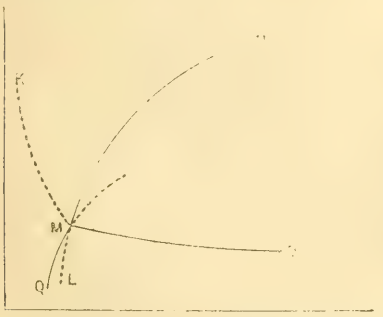
plaining by analogy the law which has operated in producing many otherwise unaccountable conditions of custom, religion, or institutions, of which the successive phases of thought, having never been embodied in tangible forms or committed to writing, cannot be reproduced or arranged in their true order of succession. The sequence therefore is often lost, and wrong causes are assigned to them. A. PITT RIVERS

Hot Ice

HAVING read a paper before the Owens College Chemical Society on January 21, in explanation of Dr. Carnelley's experiments, in which I treated the subject in a similar way to Dr. Pettersson, perhaps I may be allowed to point out one or two differences in my explanation from that given by Dr. Pettersson in NATURE, vol. xxiv. p. 176.

In the first place Dr. Pettersson speaks several times of the point *m* (the triple point) as being 0°·0078 C. below zero, whereas it must be above, because the melting-point of ice rises as the pressure is diminished.

After describing the line *m k*, which I believed then to exist, and which will probably be found really to exist if ice can be



heated, Dr. Pettersson says that in the case of ordinary ice it has been proved that ice does not get hot, and that the limit of the ice-surface is along *l m*, a continuation of the water-steam line *m n*.

Now Prof. James Thomson describes *m* as the point of intersection of three different lines, *n m*, *d m*, and *q m*, the water-steam, water-ice, and ice-steam lines; *m q* being, not a continuation of *n m*, but a separate line, the difference in position being due of course to the latent heat.

I fail to see also how *m k* can be considered a continuation of *d m*, any than more of *n m*. Lastly, after denying the possibility of ordinary ice becoming hot, Dr. Pettersson describes Dr. Carnelley's ice as condensed and not frozen. In those experiments of Dr. Carnelley's which I have seen, the water was frozen round the thermometer, and not condensed on it. The matter therefore seems to stand thus:—If the ice does really become hot, the limit of the ice-surface is most probably along *m k*, whereas if Mr. Hannay and others are correct in stating that the temperatures of the ice and condenser are identical, the limit must be along *m q*, and not along *m l*, which latter is the line denoting the maximum tension of the vapour of water cooled below the freezing point without solidifying, and not of ice below the freezing point.

I would just say also that the idea of an allotropic modification of ice did not occur to me.

SYDNEY YOUNG

The Owens College, Manchester

Note on Piczorhynchus melanocephalus (Ramsay), and Ptilopus viridis (Ramsay), from the Solomon Islands

HAVING lately received several specimens of the Piczorhynchus, which I described under the above name, I find that it is the young of Mr. Tristram's *P. vidua* (see *Proc.* Linn. Soc. of New South Wales, vol. iv. p. 468) from the Solomon Islands. The white collar which commences on the nape is much broader in the young than in the adult, and the feathers of the chest are white, all margined conspicuously with black.

Specimens have been obtained on the island of "Ugi," one of the Solomon group.

I believe the fruit pigeon I determined as *Ptilopus viridis*, from the Solomon Islands, will prove to be the female of *Ptilopus argenticæ*, Gray, of which I have recently seen some fine specimens collected by the Rev. George Brown and Lieut. Richards, R.N., at "Ugi." ED. P. RAMSAY

Anatomical Museum, Sydney, April

THE BRITISH MUSEUM CATALOGUE OF BIRDS[1]

AS has been more than once remarked in our pages, it would require more than one man's lifetime to complete the Catalogue of Birds, if the rate at which the first four volumes were produced had to be continued. Mr. Bowdler Sharpe, who has written these first four volumes, was a young man when he commenced his task, but at the same rate of progress it would have required him to live nearly a hundred years to finish the Catalogue by himself. Dr. Günther has therefore had to seek assistance from outside the walls of the Museum, and has engaged the services of Mr. Seebohm to bring out the fifth volume of the Catalogue, which contains a description of the family *Turdidæ*, containing the Thrushes and Warblers. As Mr. Seebohm has devoted several years to a study of this family, he possesses a special knowledge of his subject probably unequalled by any other ornithologist. It must be remembered that, as in the case of Dr. Günther's Catalogue of Fishes, the Catalogue of Birds is not a mere list of specimens in the national collection, but is in reality a monographic *résumé* of the birds of the world. If we look through the first four volumes of this laborious work we shall find that not only are the species in the British Museum thoroughly described, but that species not included in the collection of that institution are also treated of, and the types of rare birds in Continental museums are fully described; showing that Mr. Sharpe was not content to work solely with the collection under his charge, but that he has compared his notes with the specimens in many of the museums of Europe, and has therefore done his utmost to make the Catalogue in every way complete. But if this is true of the first volumes, it is ten times more so in the case of the fifth, which now lies before us. On turning over its pages we see that Mr. Seebohm has not only visited European museums, but has even

[1] Vol. V., Containing the Family *Turdidæ*, by Henry Seebohm.

been to America for the purpose of examining types, and the result is that up to the date of publication his work must be as complete as personal labour and an unlimited expenditure of time and money could render it. Again, the author's well-known travels in various parts of Europe and Siberia have made him acquainted with the natural history of a number of the species described in his book, and have given him a practical knowledge which must have stood him in good stead at every turn. It is not in this journal only that he will receive the meed due to his energy and perseverance, but he is sure to receive the gratitude of every ornithologist for a monograph of two such difficult families as the Thrushes and Warblers have always proved themselves to be.

Although adopting Mr. Sharpe's classification of the *Passeres*, he finds that this arrangement is artificial; but we are not sure that the arrangement of our author is altogether free from a similar charge. No one who has not studied the birds above mentioned can have the slightest idea of the extraordinary difficulty which the student would experience who tries to classify the Warblers on structural characters only, and we find no fault with Mr. Seebohm when he makes the style of coloration a generic character in these birds. But that the author himself feels a little uncertain in his key to the genera of the Warblers is shown by his introducing some of the genera three times in the *Clavis* under different sections, and it reads somewhat curiously to learn that one of the characters of the genus *Acrocephalus* is to have "the bill acrocephaline (or phylloscopine)"; the truth being that, as in the case of the species of Warblers, the genera so run one into the other that it is difficult, if not impossible, to define the exact natural limits of each. These remarks, however, almost appear hypercritical when one turns to the actual descriptive work of the author, and examines the complete way in which the synonyms are given and the descriptions elaborated, and this with the utmost conciseness consistent with completeness. One thing is evident from the list of specimens, that the British Museum series of these birds is a very full one, and we note with pleasure the constant generosity of the author himself in supplying specimens from his own collection. In the case of a bird like the common Willow Warbler, for instance, the series of specimens embraces nearly every locality whence the species is known, so that its geographical distribution is absolutely illustrated by the skins in the British Museum

In his classification of the sub-family *Turdinæ*, or True Thrushes, colour again plays an important part in classification, but we cannot complain of his arrangement, which seems to be perfectly natural, although we shall not be surprised if some ornithologists urge that some of the genera included in *Erythacus* and *Merymecocichla* have at least as good grounds for separation on the style of colour as have some of the genera allowed by Mr. Seebohm. But not only will protests be raised on the score of nomenclature of certain species, but the novel feature of hybridisation and imperfect segregation of species introduced by the author will doubtless be subjected to severe tests. His opinions on the imperfections in the code of zoological nomenclature propounded by the British Association are well known, but the critic who attempts the task of dealing with the author on this point must clear himself of the charge (only too true we fear) that he knows of no writer who attempts to carry them out in their entirety. Mr. Seebohm observes (Introduction, p. 11): "I have accordingly adopted the law of priority with the following modifications:—that names which have been extensively misapplied must be rejected, and names otherwise unobjectionable must be retained, if a majority of ornithological writers have used them, even though they may not be the oldest. The adoption of this conformation of the law to the practice of the good old times would also have another immense advantage. It would enable us to omit the authority for the specific name, as all the names would henceforth be *plurimorum auctorum*, and thus the stigma that our names are after all trinomial would be avoided." We must demur to this reasoning, which is heterodox enough to cause the shade of Strickland to arise, and will doubtless bring forward protests from many surviving framers of the British Association code. But we ourselves feel that this practice would very often cause a manifest injustice to the early writers, and we think that this is proved in some instances by Mr. Seebohm himself, as for instance with the name of the Dartford Warbler, which he calls *Sylvia provincialis* (Gmel.), although he admits that Boddaert's name of *Motacilla undata*, published five years before Gmelin's work, and admitted by such authorities as Prof Newton and Mr. Dresser, is referable to the species. Boddaert's name is founded on the *Pitte-chou de Provence* of Daubenton, and Mr. Seebohm himself admits that "the figure is sufficiently good to leave no reasonable doubt as to the species intended to be designated; and Boddaert's name may therefore be held to be 'clearly defined.' Nevertheless there seems to be no sufficient reason why the name in common use should be changed." Here we consider that the long oblivion which enveloped Boddaert's nomenclature was due, not to any fault of Boddaert himself, but entirely rests with subsequent naturalists, who did not consult his work; and that therefore Boddaert has no right to suffer for the shortcomings or laziness of his successors. We are aware that the scarcity of the book makes Boddaert rather an exceptional case, but the principle applies to many of the writings of the fathers. As however the rules of nomenclature must sooner or later be re-discussed by the British Association, we may leave the defence of his principles to Mr. Seebohm himself, feeling sure that no one can read his opinions on this subject without feeling that he has a good deal to say for his view of the case.

One great feature of the present volume is the courage which the author has shown in applying the doctrine of the evolution of species to the birds as they exist at the present day. This principle was to a small extent admitted by Mr. Sharpe in his previous volumes, when he allowed the existence of sub-species, or, as Mr. Seebohm names them, con-species. The great risk that we see in Mr. Seebohm's method lies in the fact that it affords too easy a solution for otherwise difficult problems, but we must remember that the author was himself witness to the inter-breeding of the Carrion Crow and the Hooded Crow in Siberia, and we know that this also takes place in certain parts of Great Britain. Having seen this with his own eyes, and brought back to this country a large series of the hybrids, it was only reasonable for him to suppose that other birds are also capable of hybridising, and we think that the author proves his case with regard to the two Blue Rock Thrushes (*Monticola cyanus* and *Monticola solitarius*), which in certain parts of China inter-breed; and it is most curious that the vast majority of the birds found in the winter quarters of the Eastern Blue Rock Thrush, from Burmah and Malaisia to the Mollucca Islands appear to be hybrids. According to the author, *Cettia cantans* and *Cettia minuta* also inter-breed, and produce an intermediate form which he calls *Cettia cantans minuta*, a re-introduction of trinomial nomenclature which we do not at all like. The intermediate form, too, appears to be principally found in the Island of Formosa, though also met with at Chefoo, on the mainland opposite Japan, while one of the other forms is an inhabitant of Japan, with the exception of one Formosan skin in the author's collection, and the other is said to breed in South China and Hainan. Of these three forms then we should suppose that the Formosan was the oldest bird from which the other two had developed themselves, but that they had not as yet become entirely separated as distinct species. We must wait for more evidence with regard to

the South African Chats, to some of which Mr. Seebohm has applied his principle of hybridisation, as we are not yet satisfied that the changes of plumage cannot be accounted for by the more natural process due to age or the season of the year. These few remarks will not, however, detract from the sterling merit of Mr. Seebohm's volume, which bears on every page the evidences of the careful and exhaustive work which the author bestows on every subject he handles. The eighteen coloured plates are beautiful examples of Mr. Keuleman's great talents as a natural history artist, and the colouring is much more satisfactory than in the last volume of this Catalogue, issued by the British Museum.

MAGNETIC AND AURORAL OBSERVATIONS IN HIGH LATITUDES[1]

LIEUTENANT WEYPRECHT, the noted leader of the Austrian Arctic Expedition of 1872-74, whose death is a great loss to science, recently published a little text-book embodying the results of his wide experience in Arctic observation of magnetic and auroral phenomena, which will be invaluable in pointing out to future observers the precautions and requirements which only actual experience of Arctic life can suggest, and the arrangements of apparatus and stores, which, once left behind, must be done without; frequently to the loss of opportunities for observation which do not recur. It would however be wearisome to the general reader to enter into details of Arctic work, and no one to whom the matter is of practical moment will omit reading the book itself. Some however of the precautions suggested give so vivid an idea of the difficulties and even the suffering which Arctic observers have to meet in the cause of science, that we cannot forbear a passing mention of them.

In magnetic observatories, where iron is rigidly tabooed, and uniformity of temperature is of the first importance, stoves are naturally out of the question. In winter, when the huts are thickly covered with snow, the temperature should never fall below -20° C. (-4° F.), which, as Weyprecht says, may be borne for some hours in suitable clothing without severe suffering. Good fur garments are naturally essential. The most difficult part is the sufficient protection of the feet, that found most effectual being very wide felt boots reaching to the knee, into which the feet, clad in thick woollen stockings, are packed with dry hay or straw. The hands are covered with thick woollen gloves, and whenever they are not in actual use are further protected by fur. In absolute determinations however, which have to be carried on in a separate hut, which is also used as an astronomical observatory, and hence more open to the weather, the cold is not only much more intense, but the fingers must be left bare, or at most covered with thin cotton gloves, on account of the delicacy of the instruments. On two occasions during the *Tegetthoff* Expedition such quantities of snow were driven into the observatory through the crevices of the shutters as, by loading one side of the telescope, actually to throw it off its pillar.

For absolute magnetic observations Weyprecht gives preference to Prof. Lamont's portable theodolite, which contains in itself everything necessary for the determination of declination and horizontal and vertical intensity. If however a fixed scale could be attached to the telescope for rapid readings the instrument would be still further improved.

With regard to northern light observations, Weyprecht repeats his important classification of auroral forms given in his *Nordlichtbeobachtungen*. For observations on the altitude of auroræ, with a view to calculation of height, he recommends a simple instrument consisting of a tube with an eye-piece, movable in the magnetic meridian, and with an altitude circle reading to $\frac{1}{2}^{\circ}$. The tube must be attached to the end of the axis, so as to be capable of sweeping the entire meridian. The observations should be repeated at short and regular intervals, and both the upper and lower edges of the arches should be observed, thus giving at once the mean altitude and the breadth of the bands. If the "dark segment" is visible, its mean height and the azimuth of its summit must be observed, as it probably indicates the direction of the origin of the aurora. If a corona is formed the approximate position of its centre must be observed. Another method of determining the position of the corona is by measuring the direction of the rays of which the arches are formed. This is best done by measuring their inclination from the perpendicular in two azimuths 90° apart. If the tube we have mentioned be provided with an azimuth circle and cross-wires in the eye-piece with a position circle reading to $\frac{1}{2}^{\circ}$ this is readily accomplished, the perpendicular being verified by observation of a plumb-line.

For spectral observations Weyprecht considers direct-vision instruments of good dispersion the most suitable. In low latitudes we have found a single bisulphide prism and simple slit and eye-hole without lenses to answer well, and if such an instrument were attached to the same axis as the measuring tube, which would act as a finder, we believe it would show fainter spectra than any direct vision arrangement. We do not know however how it would be affected by Arctic temperatures. Weyprecht does not mention any means of measuring the position of the lines—the simplest is Piazzi Smyth's comparison with the hydrocarbon spectrum of a spirit-lamp, and another very good scale is the band-spectrum of air yielded by a vacuum-tube fixed across the slit and made to flash as required.

Weyprecht insists on the importance of further comparisons between the movements of the aurora and magnetic disturbances, and points out the high interest that would also attach to observations of the earth-currents.

H. R. PROCTER

[1] "Praktische Anleitung zur Beobachtung der Polarlichter und der magnetischen Erscheinungen in hohen Breiten," von Carl Weyprecht, Schiffs-Lieutenant. (Wien, 1881.)

NOTTINGHAM UNIVERSITY COLLEGE

THE fine building, auspiciously opened the other day as a college in the heart of Nottingham, represents the last development of that all too tardy interest in higher education which, in the more recent years, has originated the Victoria University in Manchester, the Yorkshire College in Leeds, the Science College in Newcastle (a flourishing offshoot of Durham University), the Mason Science College in Birmingham, and others.

It is gratifying to find in a new provincial centre, with its varied activities and the usual temptations associated with money-getting, an intelligent, if somewhat late, appreciation of the thirst after knowledge for its own sake, as well as for that to which it may be profitably applied, and a disposition to take generous means of satisfying it.

Of the inception and growth of the Institution we need not here speak at any length. The elements of a college were already in existence. For seven or eight years past lecturers from Cambridge have visited Nottingham and drawn large audiences. The Government Science Classes were also highly appreciated. It is thus estimated that no fewer than 1400 students will be ready to take advantage of the instruction soon to be provided. Nottingham, moreover, has possessed a public library since 1868, and this, along with the Natural History Museum, greatly needed larger accommodation. From the union and consolidation of these and other educational agencies under one roof where the conditions of progress are much more favourable, excellent results may be anticipated. A distinctive feature of the Nottingham College is that it has been built by the Municipal

Corporation of the place, is to be held as corporate property, and will be sustained mainly out of the corporate funds. With a total cost of 70,000*l.* (or, taking into account the value of the land, 100,000*l.*) the only endowments at present are the 10,000*l.* presented by an anonymous donor, and 300*l.* from Lady Ossington (for a scholarship). It is expected that the trustees of the late Mr. F. C. Cooper will, in accordance with his will, apply some part of his estate towards the endowment of classes in the College, but it is not at present known how much. Thus the expense of maintenance will, at least in the outset, mainly fall on the town itself. The experiment will doubtless be watched with interest.

The general internal arrangement of the new building may be here briefly noticed. The library-rooms are in the eastern wing, to the left of the principal front, and the natural history museum is housed in the other wing. The former include two reading-rooms on the ground and first floors. Behind the principal entrance are placed the three theatres for chemical, physical, and general lectures, the two former having laboratories, work-rooms, and professors' rooms attached. The largest theatre accommodates 600 persons, the chemical 220, and the physical 100. These rooms are well provided with modern appliances. In addition may be noted a balance-room, and an optical gallery 125 feet long for experiments in light.

It is stated in the report of the Organisation Committee that all persons will be admitted students who give evidence of their desire to improve their education and make advances in the acquisition of knowledge. More particularly the object of the founders of the institution seems to have been of a threefold character. First of all the College will absorb, as already indicated, the University Extension Lectures and Classes and the Government Science Classes, developing and systematising the courses of instruction in which these have been engaged. Next a technological school will be provided, and classes formed for teaching, in a more direct manner, the theoretical parts of certain trades. Once more, the preparation of students for residence at the older universities seems to have been contemplated; but this feature will probably, at least for some time, have little prominence.

For the purpose of systematic education the course of instruction has been arranged under four heads: (1) ancient and modern languages, literature, history, political philosophy and economy, logic, and philosophy; (2) mathematics, theoretical and applied mechanics, and physics; (3) inorganic and organic chemistry, pure and applied; (4) biological science, botany, zoology, and physiology; also geology and allied subjects. In the Government Science Classes (distinct from the College curriculum) instruction will be given in several of the subjects in which aid is given by the department at South Kensington. The Technological School will deal with the following among other subjects:—Cloth, cotton, silk, lace, and hosiery manufactures, weaving, metallurgy, gas manufacture, telegraphy, pottery and porcelain, bleaching, dyeing, and printing, tanning, mechanical engineering, oils, colours, and varnishes. It is to be distinctly understood, however, "that these classes are not so much for teaching trades as for teaching those subjects which underlie work and bear upon trade, and help to develop the intellect of the workmen."

The scheme of education provided will thus be seen to be of a comprehensive nature. All who are solicitous that England should take a good place among the nations in industrial competition will be glad to see a new technical school added to the few we already possess. The number of these schools will have to be greatly multiplied before we have anything like the advantages of Germany in this respect. In this connection we may direct attention to an interesting little volume recently written by Mr. Felkin (a native of Nottingham, by the way) who has carried on the manufacture of hosiery in Chemnitz, Saxony, since 1861, and describes what is being there done in the way of technical instruction, and its results. (Mr. Samuelson criticises the system in the *Fortnightly* this month.) The aspects of such technical education are various, and not the least in importance is that the workman, who is thereby enabled to feel an intelligent interest in his work, to comprehend the scientific principles on which it is based and the conditions of excelling in it, and to seek to do it as well as he possibly can, becomes conscious of mental growth and expansion. He even thus acquires new vistas (to use Prince Leopold's expression), and finds the drudgery of routine materially lightened. For those again who seek culture in different directions (scientific or literary) from that bearing on their daily work, a wide range of subjects is presented for choice. The cultivators of science for its own sake will doubtless not be wanting, and some excellent solid work, we trust, will be done. The youth seeking to be trained for a scientific career, and the working lad ardently pursuing some favourite study in his scanty hours of leisure, may alike resort to the College for stimulus and direction.

In the strong reaction which has become evident in recent years from that neglect of science which was so long prevalent among us, it has appeared to some that there is now an objectionable tendency to onesidedness in education. However this may be, the founders of the new College have determined, and we think wisely, that it should be more than merely a college of science and technical institute, and the purely literary elements of culture are included.

The requirements of the industrial population will be respected by the holding of classes in the evening, and the adoption of lighter fees than those for the day-students. The teaching will be conducted by resident professors, non-resident lecturers, and local teachers; and the student, after passing through the regular course of instruction and training, will, on passing an examination, receive a certificate.

The four professors required for the curriculum have been appointed as follows:—Professor of Language and Literature, Rev. J. E. Symes, M.A.; Professor of Mathematics and Mechanics, Dr. J. A. Fleming, B.A.; Professor of Chemistry, Dr. F. Clowes, F.C.S.; Professor of the Biological Sciences, Rev. J. F. Blake, M.A. One of the professors will act as Principal or Dean, with some extra emolument.

The University College of Nottingham, in fine, begins its career with good promise of usefulness, and it is to be hoped that wealthy and liberal friends of education will respond in a practical way to the appeal of the College Committee, who "desire it to be known that they are prepared to receive endowments in aid of the funds of the College." We hope soon to hear that the burden of maintenance for the townspeople has been thus happily diminished.

ANTHROPOLOGY[1]

TO those readers whose knowledge of ethnology or anthropology has been derived from a perusal of Prichard's "Natural History of Man," or the compilations of Wood, Brown, Peschel, or Brace, the present work will present a surprising amount of freshness and originality. They will in fact find themselves introduced to a new and very captivating science. Instead of the disconnected, and often confusing accounts of the numerous races, families, and tribes into which mankind have been divided, with separate details of the appearance, manners, customs, houses, implements, weapons, and ornaments of each, the reader of the present work will be shown how

[1] "Anthropology: an Introduction to the Study of Man and Civilisation, by Edward B. Tylor, D.C.L., F.R.S. With Illustrations. (London: Macmillan and Co., 1881.)

mankind may be studied in a logical, connected, and far more interesting manner, by the method of comparison, and by tracing the growth or development of those faculties which more especially distinguish him from the lower animals. Everywhere he will find proofs of the essential unity of man; whether in the close similarity of the forms of the stone implements and weapons found in the most remote parts of the earth, and among the most varied races; in the identity of signs and gestures, and the striking resemblances even among the most diverse languages; or in the wonderful similarity and often identity, of habits, customs, ideas, beliefs, and religions among all savages, and the curious way in which traces of these can often be found in the very midst of modern civilised society.

It is very difficult to give any adequate idea of a work of this kind, which, in a moderate compass, contains the essence and outcome of all modern research on the various branches of the study of man and civilisation; but we shall perhaps best exhibit its wide scope and systematic treatment by an enumeration of the subjects discussed in the several chapters, adding a few remarks or criticisms where called for.

The first chapter contains a brief sketch of what we learn from history, archæology, and geology, as to man's antiquity and early condition; and in the next we are shown man's relation to the lower animals both in bodily structure and mental characteristics. These two chapters might, with advantage, have been considerably enlarged, as they constitute the foundation, and, to many persons, the most interesting portions of the modern study of man. The results hitherto arrived at by these branches of study, are, besides, both suggestive and important, and might, we think, have been more expressly referred to. The numerous remains now discovered of prehistoric man, and of his works, dating back to an undoubtedly vast antiquity, show us in no case any important deviation from the existing human type, nor any indication that his mental status was lower than (if so low as) that of many living races. At the same time the increasing rudeness of his implements as we go back, undoubtedly indicates that we have made some approach towards the period when he first emerged from the purely brute state and became "a tool-using animal." We find him in the remote past surrounded by a number of huge mammalia, including many carnivora of greater size and destructive power than any that now exist, and we know that at a still earlier period these animals were even more abundant and more destructive; yet man must have held his own against them during the time when he had not yet begun to make tools or use fire. How did he do this without the possession of some additional natural weapons or faculties, of which nevertheless we find no trace in the earliest remains yet discovered? Again, the whole bearing of the evidence as to the development of man, indicates that the point of union or of common origin of man and the anthropoid apes, is enormously remote. Each of the existing types of these great apes possesses some specially human characteristic wanting in the others (for an enumeration of which see Mivart's "Man and Apes"), and this indicates that the common origin of these apes is of less remoteness than the common origin of them all and of man. How immensely remote, then, must be this point of common origin, and what a long and complex series of diverging forms must have existed, always in sufficient numbers to hold their own against their numerous competitors and enemies! The evolutionist *must* postulate the existence of this long series of divergent forms, yet notwithstanding the richness of the Tertiary deposits in many parts of the world no trace whatever of their actual existence has yet been discovered. The extreme remoteness of the origin of man is also shown by the facts, that neither the size nor the form of the cranium of the prehistoric races shows any inferiority to those of existing savages, while the approximate equality of their mental powers is shown by the ingenious construction of weapons and implements, and the artistic talent which we find developed at a period when the reindeer and the mammoth inhabited the south of France. It has been argued that the inferiority of the early implements shows mental inferiority, but this is palpably illogical. Did Stephenson's first rude locomotive—the *Rocket*—show less mind in its constructor than the highly-finished products of our modern workshops? Or were the Greeks mentally inferior to us because they had rude cars instead of locomotives, and had no clocks, water-mills, steam-engines, or spinning-jennies? It is forgotten that arts are a growth, and have little relation to the mental status of the artificer. A number of European infants brought up among savages would not, probably, in many generations, invent even the commonest implements and utensils of their ancestral homes; and it is difficult to say how slow may have been the development of the arts in their earliest and by far most difficult stages. It is therefore by no means impossible that the makers even of the palæolithic implements may have been fully equal, mentally, to existing savages of by no means the lowest type.

In the next chapter we have an excellent sketch of the chief races of man copiously illustrated by portraits, mostly from photographs and very characteristic. Among the best are those of the Andaman Islanders and the Dyaks, which we here reproduce. The Malays are less characteristic, this race being in fact better represented by the cut of the two Cochin Chinese at p. 98.

The four chapters on Language, whether manifested by gestures and signs, by articulate speech, by pictures, or by written characters, are exceedingly interesting and instructive, especially the account of the gesture language and the illustrations of how connected stories may be told to the deaf-and-dumb quite independently of any knowledge of alphabetical or even verbal signs. Picture-writing, as exhibited in the works of savages, in Egyptian hieroglyphics and in the modern Chinese characters, is also well explained, and is so interesting that one wishes the subject were more fully gone into. In treating of the origin of language Mr. Tylor doubts the sufficiency of the theory that emotional, imitative, and suggestive sounds were the basis on which all languages were founded, though he gives tolerably full illustrations of how roots thus obtained became modified in an infinite variety of ways to serve the growing needs of mankind in expressing their wants or their feelings. He impresses on his readers the important fact that language is always growing and that new words are continually made "by choosing fit and proper sounds." He shows how words once imitative or emotional have been often so changed and modified as to have their original character totally concealed; yet he concludes, that—"it would be unscientific to accept all this as a complete explanation of the origin of language"—because "other causes may have helped." It seems, however, to the present writer, that the imitative and emotional origin of language is demonstrated by a body of facts almost as extensive and complete as that which demonstrates the origin of species by natural selection; and that the "other causes" are in both cases exceptional and subordinate. As the examples of imitative words given by Mr. Tylor are comparatively trivial and altogether inadequate, it may be well to call attention to the wide and far-reaching character of such words, and to show how much of the force, expressiveness, and beauty of our language (as of most others) depends upon them.

Putting aside all mere representations of animal sounds—as the *whinny* of the colt, the *mew* of the cat, or the *bleat* of the sheep—let us consider what an immense number of natural sounds are named by words which we at once see to be appropriate representations or imitations of them. Such are—*crash*, *whizz*, *fizz*, *hiss*, *creak*, *whistle*, *rattle*, *bang*, *clang*, *flop*, *thud*, *clap*, *roar*, *snore*,

groan, moan, wail, thunder. In other cases sights, sounds, or feelings, are represented by their accompanying or appropriate sounds. We see a *splash*, or a *slop;* we feel a thing to be *smooth* or *rough*, or to *vibrate;* and we *shiver* with cold or *terror*. Again, how many actions and qualities are represented by words expressing the sounds which sometimes accompany them—as *knock, shock, crack, snap, ring, whisper, hush, sigh, sob, wash, squash, crush, crunch, rip, rend, grind, scratch, split, spit, cough, sneeze, wheeze.* How characteristic are such words as *sticky, flicker, flutter, hurry, flurry, stumble, hobble, wobble.* Here we have not only sound, but motion and quality, represented by the arrangement of letters and syllables. How clearly do such words as *slide, glide*, and *wave* imply slow and continuous motion, the movement of the lips while pronouncing the latter word being a perfect double undulation. How curiously do the tongue and palate seem to be pulled apart from each other while pronouncing the words *glue* or *sticky*. How marked is the contrast between the harsh consonants used to express *rough, rugged*, and *gritty*, as compared with the soft flow of sounds in *smooth, oily, even, polished.* Look again at

Andaman Islanders.

the sense of effort and feeling of grandeur in pronouncing the words *strong, strength, power, might*, as compared with the opposites, *weak, faint;* or the open-mouthed sounds of *grand, huge, monstrous, vast, immense, giant, gigantic*, as contrasted with the almost closed lips with which we say *small, little, tiny, minute, pigmy, midget.* So *crawl* and *drag* are pronounced slowly as compared with *run, fly*, or *swim;* while *difficult* and *easy* express their own meaning while we pronounce them. Many objects and substances have names curiously corresponding with their qualities. We have already noticed *glue* as indicating stickiness, but no less clearly is *oil* smooth; while *brass* and *glass* indicate resonance; *tin* a tinkling sound; *lead* and *wood* a dull sound or *thud;* in *bell* we imitate its sound, while the word *jelly* indicates the shaking of the substance. In *ice* we hear the interjectional *sh* of shivering with cold; in *fire* the flicker of the ascending flame. In other cases the motion of the breath gives an indication of meaning; *in* and *out, up* and *down, elevate* and *depress*, are pronounced with an inspiration and expiration respectively, the former being necessarily accompanied with a raising, the latter with a depression, of the head. When we name the *mouth* or *lips*, we use labials; for *tooth* and *tongue*, dentals; for the *nose* and things relating to it, nasal sounds; and this peculiarity is remarkably constant in most languages, civilised and savage. Among the Malay races, for instance, we find such words as *mulut, bawa, mohon*, and *moda* for mouth; *gigit, nisinen, nigni*, and *niki* for teeth; and *idong, ugerun* and *usuut*, for nose. So in words for *large* we find a prevalence of broad sounds involving a wide opening of the mouth, as *busār, bākè, bāgut, lāmu, elāmo, tlāhé, erāāmei, aiyuk, māina*—and for *small*, words that are pronounced quickly and with slight opening of the lips, as *kichil, chili, kidi, köi, roit, kemi, anan, kiiti, fek, didiki*, all taken from languages of the Malay Archipelago.

Dyaks.

These few examples, which might be greatly increased, indicate the variety of ways in which, even now, after all the modifications and development which language has undergone, sound still corresponds to sense; and if the reader will turn to Dr. Farrar's suggestive little work on the "Origin of Language," he will find how wonderfully, by the help of analogy and metaphor, the uses and meanings of simple words and sounds have been indefinitely increased, so as to subserve the growing need of mankind to express more and more complex ideas. Mr. Tylor is rather unfortunate in his illustration of words for the form of which no cause can be assigned, when he says: "There is no apparent reason why the word *go* should not have signified the idea of coming, and the word *come* the idea of going." But, in accordance with the examples already

given, there *is* a very good and sufficient reason. We pronounce *come* with a closure and contraction of the lips and usually during inspiration, *go* with open and protruding lips and usually during expiration. Now many savages point with the lips as we do with the finger, signifying *there*, by protruding the lips in the direction to be indicated; and any one who has seen this curious gesture must be struck with its close similarity to the protrusion of the lips in pronouncing the word *go*. The same difference of the nearly closed or open lips characterises the words for these two ideas in many other languages. In French we have *viens* and *va*, in German *komm* and *geh*, in Italian *vieni* and *vai*, showing that words in distinct languages differing greatly in spelling and pronunciation may yet have a common character in the mode of speaking which indicates their common meaning.

The five following chapters treat of the Arts of Life, a subject which Mr. Tylor has to a great extent made his own, and which he discusses in a very interesting manner. The doctrine of development in the arts is however somewhat strained when it is implied that the modern gun is an outgrowth of the South American or Indian blowtube; while the origin of bank notes, and the account of the rise and progress of mathematics are hardly anthropology.

The next two chapters discuss the ideas of savage man as to the spirit-world, and the origin and development of myths; while the final chapter gives an admirable sketch of man as a social being, and of the development of that complex organism, Society. This thoughtful chapter cannot be epitomised, but the reader will find in it much curious information as to the sources of many of the customs, laws, and observances of civilised life, which are shown to be often traceable among the lowest savages. The following passage will serve to illustrate the author's style and treatment of his subject:—

"Much of the wrong-doing of the world comes from want of imagination. If the drunkard could see before him the misery of next year with something of the vividness of the present craving, it would overbalance it. Oftimes in the hottest fury of anger, the sword has been sheathed by him across whose mind has flashed the prophetic picture of the women weeping round the blood-stained corpse. The lower races of men are so wanting in foresight to resist passion and temptation, that the moral balance of a tribe easily goes wrong, while they are rough and wantonly cruel, much as children are cruel to animals through not being able to imagine what the creatures feel. What we now know of savage life will prevent our falling into the fancies of the philosophers of the last century, who set up the 'noble savage' as an actual model of virtue to be imitated by civilised nations. But the reality is quite as instructive, that the laws of virtue and happiness may be found at work in simple forms among tribes who make hatchets of sharpened stones and rub sticks together to kindle fire. Their life, seen at its best, shows with unusual clearness the great principle of moral science, that morality and happiness belong together—in fact that morality is the method of happiness."

The reader who wishes to know what is the outcome of modern research into the nature, characteristics, and early history of man; and into his progress in the arts of life, in morality, and in social economy, will find a store of valuable information and much suggestive remark in this carefully-written but unpretending volume.

ALFRED R. WALLACE

NOTES

WITH regard to the forthcoming session of the American Association in Cincinnati, to begin August 17, we have to add to information already given (p. 146) that all the meetings, general and sectional, will be held under one roof, that of the Music Hall and Exposition Buildings. On the evening of the first day of meeting there will be a citizens' reception. An afternoon is to be devoted to visiting the Zoological Gardens. An exhibition of scientific apparatus, appliances and collections will be held during the Association meeting. The objects displayed will be kept over for the ninth Cincinnati Industrial Exposition in September. After the adjournment of the Association excursions will be organised on the Cincinnati Southern Railroad, and also, it is hoped, to the Mammoth Cave.

THE Prince of Wales is expected to lay the foundation-stone of the Central Institution of the City and Guilds of London Institute, on Monday next, at 3.30 p.m. His Royal Highness and the Princess of Wales were present at the Lord President's reception on Wednesday night at the South Kensington Museum. Prior to the reception the Prime Minister and several members of the Cabinet visited the Science Schools.

WE regret to announce the deaths of Dr. E. Zaddach, director of the Zoological Museum at Königsberg, who died on June 5 last; of Dr. Wilhelm Gottlob Rosenhauer, Professor of Philosophy at Erlangen University, who died on June 13, aged sixty-eight (on the same day on which Medical Science lost Josef Skoda at Vienna); of Dr. Matthias Jakob Schleiden, the well-known botanist, and author of many works on natural history (amongst which we may point out as standard works "Die Pflanze" and "Das Meer"), who died at Frankfort on June 23, aged seventy-seven; of Dr. Theodor Benfey, Professor of Philosophy at Göttingen University, a celebrated orientalist and linguist, whose death occurred on June 26 at the age of seventy-two; and of Dr. Rudolf Hermann Lotze, Professor of Philosophy at Berlin University, author of the "Mikrokosmus," who died on July 1, aged sixty-four years.

MESSRS. SIEMENS have received advice of the completion of the new Atlantic cable recently constructed by them. The reports of insulation and working speed are highly satisfactory. The cable connects Sennen Cove, Land's End, with Dover Bay, Nova Scotia, direct, a length of 2500 nautical miles.

M. PASTEUR has received the Grand Cross of the Legion of Honour.

M. WURTZ, the present president of the Academy of Science, has been appointed Life Senator by a very large majority. This highly-approved appointment raises to three the number of members of the Academy of Sciences who now belong to the Upper House of the French Republic; the two others are M. Robin and M. Dupuy de Lome. M. Berthelot, another member of the section of chemistry, has been proposed for a seat which is at present vacant, and his election is considered quite certain. A large number of the French senators belong to the other section of the Institute, which is now taking such a prominent part in French politics. This influence of the Institute was contemplated by M. Thiers, and his views are advocated principally by Mr. Barthélemy St. Hilaire, the Minister for Foreign Affairs and Member of the Academy.

SIXTY French members of the Congress of Electricians have been appointed by M. Cochéry, the Minister of Telegraphs, who has been made President. M. Ferry, Minister of Public Instruction, has been appointed Vice-President, and four other members of the Cabinet will be chosen by the Congress. The Academy of Sciences and other public scientific institutions will appoint their own representatives, as well as foreign nations.

WE have received the sixth report of Mr. Crookes and Professors Odling and Tidy, to the President of the Local Government Board, on the London Water Supply. It relates to the quality of water supplied from May 20 to June 30, and is highly favourable. "The results of our six months' work" (say the authors),

"and the examination during this period of 1127 samples, enable us to state that as an excellent drinking supply it [*i.e.* the water supplied to London] leaves nothing to be desired."

THE Royal Archæological Institute, of which Lord Talbot de Malahide is president, holds its annual congress at Bedford this year from Tuesday, July 26, to Monday, August 1. Elstow Church, Woburn Abbey, the Roman camp and amphitheatre near Horbury and Sandy, St. Alban's Abbey, and the ruins of Old Verulam, are among the places set out in the programme to be visited.

IN the Archives of the Observatory of Stockholm the assistant, M. Lindhagen, has made a highly interesting discovery. It consists of a copy of a treatise by Copernicus which is more complete than all those known hitherto, and which thus fills a gap in the works left by the great astronomer. The treatise bears the title, "Nicolai Copernici de hypothesibus motuum cœlestium a se constitutis commentariolus." It is bound with a copy of Copernicus' "De revolutionibus orbium cœlestium," which formerly belonged to Hevelius, the Danzig astronomer. The treatise, with an introduction by Lindhagen, will shortly be published in the *Transactions* of the Stockholm Academy of Sciences.

THE Annual Report of the Royal Society of New South Wales for 1880 states that thirty-six new members were elected during the year; the actual increase is twenty-two, and the present number of members 452. One honorary member, Sir J. D. Hooker, was elected; and Mr. Hyde Clarke, Major-General Sir E. Ward, and Mr. F. B. Miller were elected corresponding members. The Clarke Medal for 1881 has been awarded to Prof. McCoy of Melbourne University, for his distinguished researches in the Palæontology of Europe and Australia; (Prof. Owen, Mr. G. Bentham, and Prof. Huxley have been the three previous recipients). The finances of the Society are in a satisfactory condition. At the annual meeting on May 4, Prof. Smith, the retiring president, gave an address, in which he reviewed the twenty-five years of the Society's existence (eleven years of which it had the name of the Philosophical Society). Up to 1875 the Society had a somewhat chequered career. It entered the new building that year, and the tide of prosperity still enjoyed is largely due to the zeal and energy of Prof. Liversidge and Dr. Leibius, the secretaries then appointed. During the past year twenty-eight papers were read by thirteen members, many of them involving much laborious research. Mr. H. C. Russell was elected president for the coming year.

CONSIDERABLE progress has been made with the building for the zoological station at Watson's Bay, near Sydney, due to the initiative of Baron Maclay. The building is a neat cottage providing five workrooms and two bedrooms, besides storeroom and bathroom in the basement. It is not intended to make a charge for each table or workroom as at Naples; but every naturalist will be expected to contribute a small sum (say five shillings a week) towards paying a caretaker. Other current expenses will have to be met by subscriptions. The Government has agreed to double the subscriptions for establishing the station up to 300*l*. The Royal Society of New South Wales may be expected to carry forward the enterprise with spirit, and assistance has been promised by the Royal Society of Victoria and other bodies there.

THE French Government have sent a scientific expedition to Mesopotamia and Assyria. An architect and an engineer accompany the expedition.

AN Astronomical Congress will be held at Strassburg during September next, and will be visited by many eminent astronomers from all parts of the civilised world. Strassburg was chosen because in its new observatory the best and most modern astronomical apparatus are to be found.

IT is said that MM. Siemens have renounced the idea of constructing an electrical railway in Paris, as the Municipal Council has not granted to them the concession they required. We believe that the railway which is to be made will be worked with Faure accumulators.

WITH reference to Mr. Newberry's letter on American cretaceous flora, in our issue of 30th ult., we are requested to state that Mr. J. Starkie Gardner is at present travelling in Iceland, and his silence may be thus accounted for.

THE meeting of Austrian Anthropologists and Antiquaries will be held at Salzburg on August 12 and 13 next.

THE Committee of the Liebig Institution at Munich has made an award of two gold medals for 1881: one to Prof. G. Hanssen of Göttingen, the other to Prof. H. Settegast of Berlin, in recognition of their great merit in the furtherance of German agriculture.

THE Berlin Medical Society are now making preparations for celebrating the twenty-fifth anniversary of Dr. von Virchow's professorship. The celebration will probably take place on October 13 next, Virchow's sixty-first birthday.

AN International Alpine Congress will be held at Salzburg in the latter half of August, upon the occasion of the ninth annual meeting of the German and Austrian Alpine Club. The following subjects will probably be discussed:—(1) On the method of surveying Alpine territory and the multiplication of Alpine maps, with an exhibition of maps executed in Bavaria, England, France, Italy, Austria, and Switzerland. (2) On glaciers and the various methods of studying the same, with special reference to the observations at the Rhone glacier and to the glacier-book of the Swiss Alpine Club. (3) On the construction of shelter-huts and their interior arrangement, with an exhibition of models and plans.

AT Hermannstadt a Transsylvanian Carpathian Club has just been formed after the model of the German and Austrian Alpine Clubs. Its object is the scientific investigation of the Transsylvanian Alps with their glens and caves. The new club numbers a good many members already, and branches have been established at Broos, Kronstadt, Mühlbach, and Schässburg.

AT Leipzig a new Ornithological Society has been formed, which numbers amongst its objects the general protection of birds.

DURING the last days of May the whole neighbourhood of Kamenz was visited by strange guests. Enormous swarms of *Libellula quadrimaculata* passed over the valley, here and there in dense masses, and extending from five to ten miles in breadth. The first swarm arrived about noon on May 30, its passage occupied two hours; in the evening a second swarm came from the direction of Weisswasser. The third swarm arrived on the morning of the 31st. Swarms of this description have not been observed since June, 1825. At Dresden the strange phenomenon was also observed.

A BURIALPLACE has been discovered in the neighbourhood of Naumburg, which proves to be a rich store of antiquities. Up to the present some ninety clay vessels and bronze objects have been excavated, amongst which is a very large ash-urn.

IN a peat bog near Triebsee (Stralsund district) a discovery of flint implements has been recently made. Some four or four and a half feet below the surface eight lance-points and fourteen edge tools were found lying in a heap together. Although the whole neighbourhood and the Island of Rügen are rich in objects of the kind, the large size of the present specimens and

the perfection of the workmanship cause general surprise. The objects found have been forwarded to the Stralsund Museum.

THE Thuringian Fisheries Union had a meeting at Jena on June 7, when the Grand Duke was present. The proceedings proved the satisfactory progress of pisciculture in Thuringia.

A NEW commentary to Kant's "Kritik der reinen Vernunft" will be published by Spemann of Stuttgart, upon the occasion of the centenary of that great work. The author is Dr. H. H. Vaihinger of Strassburg, and the commentary will be in four volumes. It will give a detailed explanation of the text, a logical analysis of the contents, and an abstract of all the works published during the century with reference to Kant's masterwork.

SIMILAR devastations to those which we reported from the Caucasus some time ago are now caused in Turkey by grasshoppers. The Turkish Government is compelled to employ extraordinary measures to overcome the plague. A particularly voracious species has appeared in the Bodirum district (Smyrna), and the whole population is employed to combat the insects. At Angora all business was suspended for three days by order of the Governor-General, and all the inhabitants were ordered to march out into the fields to destroy the grasshoppers. Every inhabitant was compelled to deliver 20 oka (about ½ cwt.) of dead grasshoppers to the officials. The swarms are said to emanate principally from Persia.

THE Epping Forest and County of Essex Naturalists' Field Club has held three field-meetings this year. On April 2 the Club visited Waltham Abbey under the guidance of Mr. George H. Birch, who communicated a paper on this interesting building. On May 14th the Club united with the Geologists' Association for the purpose of visiting the chalk-pits at Gray's Thurrock. The conductor for the occasion was Mr. Henry Walker, F.G.S. Prof. Morris, who was also of the party, gave a series of most instructive addresses on the ground. The last field-meeting, held on June 25, was microscopical, the conductor being Mr. W. Saville Kent, F.L.S. The Club met at Chigwell, where they were hospitably entertained by the Rev. Linton Wilson, M.A., at Oakhurst. Mr. Kent read a paper entitled "Infusoria—what are they?—their Collection and Investigation." Field-meetings in conjunction with the Hertfordshire Naturalists' Field Club and with the Essex Archæological Society are under arrangement. The Essex Field Club has recently been making excavations in the ancient earthwork in Epping Forest known as Ambresbury Banks, under the superintendence of General Pitt-Rivers, F.R.S., who will shortly give an account of the results obtained.

IN the Poserna district, between Weissenfels and Lützen, saline springs have been discovered by the Mining Engineer, Herr C. Reyher of Halle. The spring near the village of Poserna comes from an old shaft which is said to be eighty yards deep, but is now filled with *débris*. The water is effervescent. Another spring was discovered near Stösswitz at a depth of 19 metres, and rose with such force that it could only be stopped with great difficulty. Some 100 yards from the latter a third spring was discovered. The water of the three springs is strongly saline, and as they contain principally potash salts, their discovery is valuable. It is now found that during the fifteenth century salt works existed in this neighbourhood.

M. THOREL, President of the General Council of the Seine, has received an official answer to his inquiries relating to the reasons why the Paris gas companies refused to sell their commodity to Parisian aëronauts. It is probable that an arrangement will soon be entered into, and that public ascents will be resumed shortly as in former years, under the supervision of the municipal authorities.

THE Kant Society at Königsberg inaugurated a chapel dedicated to the memory of Kant on June 19. The small Gothic building touches the cathedral on the north side and forms a fitting substitute for the "Stoa Kantiana," which has become useless since the opening of the new University building. The interior of the chapel is formed by a double cross vault. On the left the same tombstone is let into the floor which covered the grave in the "Stoa Kantiana," and which was originally presented by Herr Scheffner. Underneath this the remains of Kant are contained in a double zinc coffin.

AT Zamoly, in the Hungarian Comitat of Stuhlweissenburg, two tombs have been discovered which contained coins from the time of Diocletian. One was the grave of a boy, the other that of a very tall man. Interesting remains of bas-reliefs and portraits were found in the tombs. They were on pieces of wood; one shows the words "Bibite hoc."

THE *Journal Télégraphique* of Berne, the organ of international telegraphy, has expressed its approval of the proposal to establish an international code for the protection of submarine telegraph property, both during war and peace.

THE German Geometrical Society held its tenth annual meeting at Karlsruhe in the third week of June.

ON the 16th inst. an International Agricultural Exhibition will be opened at Hanover. The exhibitors number over 1600.

MR. MURRAY has in hand, and will shortly publish, the following works of interest to scientific men:—"The Land of the Midnight Sun," being an account of Summer and Winter Journeys through Sweden, Norway, Lapland, and Northern Finland; with Descriptions of the Inner Life of the People, their Manners and Customs, the Primitive Antiquities, by Paul B. du Chaillu. In two vols.; with map and numerous illustrations. "The Formation of Vegetable Mould through the Action of Worms," with Observations on their Habits. By Charles Darwin, F.R.S. "The White Sea Peninsula;" a Journey to the White Sea, and the Kola Peninsula. By Edward Rae. With illustrations. "The Life of Sir Charles Lyell;" with Selections from his Journals and Correspondence. Edited by his sister-in-law, Mrs. Lyell. With portrait, two vols.

DURING the demolition of some old buildings at 406 and 407, Oxford Street, last week, the workmen on reaching the foundations came on a quantity of old armour and weapons—helmets, breastplates, spears, swords, and daggers, some very curious in shape. On opening a stone vault they found also some plate, including church utensils, such as a monstrance and a chalice, the workmanship of which is thought to be of the fourteenth century. The monstrance had a Latin inscription.

AN Agricultural Exhibition will be held at Strassburg from September 11-18 next. Over 2000*l.* will be distributed in prizes.

THE additions to the Zoological Society's Gardens during the past week include a Weeper Capuchin (*Cebus capucinus*) from Brazil, presented by Mr. J. S. Chapperton; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mr. Arthur Tower; a Central American Agouti (*Dasyprocta isthmica*) from Central America, presented by Mr. A. Melhuish; two Pileated Jays (*Cyanocorax pileatus*) from La Plata, presented by Mr. A. A. Dawley; a Berg Adder (*Vipera atropos*) from South Africa, presented by Mr. Borrodaile Pillans; a Cullen's Eagle (*Aquila cullenî*), South European, eight American Menobranchs (*Menobranchus lateralis*) from N. America, purchased; a Common Rhea (*Rhea americana*) from South America, on approval; a Reeves' Muntjac (*Cervulus reevesi*), born in the Gardens; two Scarlet Ibis (*Eudocimus ruber*), three Common Widgeons (*Mareca penelope*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN

THE COMET.—By favour of Dr. W. L. Elkin of the Royal Observatory, Cape of Good Hope, we are able to subjoin observations of the great comet made at that establishment before the perihelion passage, which it is stated will admit of improvement when the places of the comparison-stars have been more accurately determined :

	Cape M.T.	R.A.	Decl.
	h. m. s.	° ′ ″	° ′ ″
May 31 ...	6 19 24 ...	75 46 25 ...	−29 42 19
June 3 ...	5 53 47 ...	76 12 30 ...	26 25 57
4 ...	5 59 57 ...	76 21 55 ...	25 4 53
9 ...	5 31 18 ...	77 16 24 ...	−15 44 53

From the positions on May 31, June 4 and 9, Dr. Elkin has calculated the following elements of the comet's orbit, by the side of which we place for comparison others deduced by Mr. Hind, from post-perihelion observations up to July 1 :—

	ELKIN	HIND
Perihelion passage, June	16·29839 G.M.T.	June 16·41519 G.M.T.
Longitude, perihelion..	264 55 13	265 9 4
,, node ...	270 54 27	270 58 0
Inclination...	63 27 4	63 29 9
Log. perihelion dist....	9·866656	9·865516
	Direct.	Direct.

The longitudes are reckoned from the mean equinox of 1881·0. Mr. Hind's orbit gives the following expressions for the comet's heliocentric co-ordinates x, y, z to be used with the X, Y, Z of the *Nautical Almanac* in the calculation of geocentric right ascensions and declinations ; they apply to apparent equinox 1881·5.

$$x = r[9{\cdot}65000] \sin.\ (v + 356\ 22'5)$$
$$y = r[9{\cdot}99187] \sin.\ (v + 243\ 20'7)$$
$$z = r[9{\cdot}96142] \sin.\ (v + 328\ 24'3).$$

Here, v is the true anomaly, r the radius vector, and the quantities within square brackets are logarithms.

We may take this opportunity of correcting a singular misstatement with which Admiral Mouchez, the director of the Observatory at Paris, is credited in the *Comptes rendus* of the Academy of Sciences. He is there made to say that the period of revolution of the comet of 1807, which had elements resembling those of the present comet, was found by Bessel to have been reduced to 174 years after he had taken account of "new perturbations." Any one who refers to Bessel's treatise will see that this is an error. Bessel fixed the period of revolution at 1713¾ years, on September 22, 1807, and in continuing the computation of the perturbations by the planet Jupiter to March, 1815, when they had become very small, he found that the revolution had been diminished thereby, about 170 years; he considered that the period he had assigned for September 22, 1807, was not liable to a greater error than 100 years. In the *Comptes rendus* the effect of perturbation on the period appears to have been quoted, instead of the revolution itself, as perturbed to March, 1815. In the communication to which we refer, the identity of the comet of 1881 with that of 1807, is pretty distinctly assumed, but the weight of evidence is certainly in the other direction.

THE VARIABLE STAR U CEPHEI.—Prof. Julius Schmidt has published an ephemeris of the last variable star discovered by Ceraski in Cepheus, extending to the end of the present year. From his later observations he has found that the gradual increase of period which he had formerly suspected is not confirmed, and he now fixes the period at 2d. 11h. 49 n. 33·35s. On August 18 commences a series of minima, which may be observed at intervals of something less than five days to the end of December : the following are the Greenwich mean times to the end of October :—

	h. m.		h m.		h. m.
Aug. 18,	14 44·9 ...	Sept. 12,	13 0·8 ...	Oct. 7,	11 16·6
